BRIGHAM YOUNG UNIVERSITY

As chair of the candidate's graduate committee, I have read the thesis of Richard C. Stephenson in its final form and have found that (1) its format, citations, and bibliographical style are consistent and acceptable and fulfill university and department style requirements; (2) its illustrative materials including figures, tables, and charts are in place; and (3) the final manuscript is satisfactory to the graduate committee and is ready for submission to the university library.

## ABSTRACT

### COMPARING THE FEASIBILITY OF CUTTING THIN-WALLED SECTIONS FROM FIVE COMMONLY USED METALS UTILIZING WIRE ELECTRIC DISCHARGE MACHINING

Richard C. Stephenson

School of Technology

Master of Science

Wire Electric Discharge Machining (wire-EDM) is a non-traditional machining process. Controlled electric sparks are successively used to vaporize part of a workpiece along a programmed path in order to machine a desired part. Because there is no tool that comes in direct contact with the workpiece, it is possible to machine thin, delicate parts.

This thesis was designed to observe and analyze the differences in cutting capabilities for a conventional wire-EDM machine when cutting thin-walled sections from five commonly used metals utilizing a variation of roughing and finishing passes. The five metals that were used in this study are: Aluminum 6061 T6, Yellow Brass SS360, 420 Stainless Steel, D2 Tool Steel at 25 to 30 RC, and D2 Tool Steel at 60 to 65 RC. The thin-walled sections were constrained on each end by the parent material to which they remained attached, and they ranged in thickness from 0.05 millimeters (0.002

inches) increasing incrementally by 0.05 millimeters (0.002 inches) until they reached a thickness of 0.30 millimeters (0.012 inches). A Sodick AQ325L wire-EDM machine was employed to perform the machining.

It was observed that differences exist in the capabilities of cutting thin-walled sections from the five different metals. This could be both observed visually through inspection and statistically through the analysis of each data set obtained by measuring the resultant thickness of each section. It was also observed that differences exist for the same material while utilizing the variations of cutting parameters: a roughing with no finishing passes, a roughing with one finishing pass, and a roughing with three finishing passes. Thus both the material properties and the cutting parameters play a significant role in determining the capability of cutting thin-walled sections with a wire-EDM machine.

## ACKNOWLEDGMENTS

It would be remiss of me to not acknowledge the help and support that has been graciously given to me in conjunction with this project and throughout my educational endeavors. Those at the forefront are the members of my graduate committee, the professors in my department, my family, and my friends. Each of these individuals has given me timely instruction, assistance, and encouragement. Each has been willing to share their insights and knowledge on this and a variety of other subjects and has made a lasting and indelible impact upon me as an individual. I express to each of these individuals heartfelt gratitude for their interest in me and my education, and for instilling in me a love of and a persistent drive towards the attainment of knowledge.

# 1 Introduction

Electrical Discharge Machining (EDM) is a non-traditional manufacturing process because no tool physically touches the workpiece. The process uses an accurately controlled electrical discharge that creates a spark between the workpiece and an electrode. Each spark vaporizes a small portion of the workpiece. As the workpiece slowly moves along its cut-path, successive sparks continually erode material in the movement direction, thereby cutting the desired part.

Many different machining applications use the theory of EDM, such as Wire Electrical Discharge Machining (wire-EDM), Electrical Discharge Milling, Electrical Discharge Grinding (EDG), Electrical Discharge Dressing (EDD), Ultrasonic Aided EDM (UEDM), Abrasive Electrical Discharge Grinding (AEDG), Micro Electrical Discharge Machining (MEDM), Micro Wire EDM (MWEDM), Mole EDM, and Double Rotating Electrodes EDM.<sup>1</sup> Wire-EDM differs from these other processes because it utilizes a wire traveling longitudinally through the workpiece as the electrode. Wire Electrical Discharge Machining (wire-EDM) is the focus of this thesis.

Due to the use of the electric spark, practically no forces are applied to the workpiece. The absence of cutting forces achieved by the EDM process creates very unique capabilities, some of which include thin, small, and delicate part machining.

---

<sup>1</sup> Dean Brink, "Different Types of Machining Processes That Use EDM," *EDM Technology Transfer* (2000), available from <http://www.edmtt.com/articlesreports/edmprocesses.html>; Internet; accessed 6 April 2006, 1-2.

## 1.1 Problem Statement

It is impractical to use traditional machining methods in order to cut thin parts due to the machining forces that are applied to a workpiece by the cutter. These cutting forces would destroy these delicate parts, and therefore other methods of machining need to be employed in order to produce the required parts. EDM is a process that should be conducive to this type of machining due to the absence of cutting forces. Although the technologies utilized in wire-EDM are relatively new, their use in the industrial sector has been rapidly increasing. However, very little research has been done in cutting thin-walled parts of less than 0.127 millimeters (0.005 inches) with conventional wire-EDM machines.<sup>2</sup> Sangseop Kim performed some research where he tested “how different materials and web thicknesses affect the capability of cutting thin walled parts.”<sup>3</sup> The thin-walled sections that Kim cut were machined in such a way so that only one end of the specimen remained attached to the parent material.<sup>4</sup> The primary objective of this study is to observe the limitations in cutting thin-walled sections, which are constrained on each end, from five different commonly used metals with a conventional wire-EDM machine while utilizing the machine’s default settings for different combinations of the roughing and finishing passes. This research differing from that performed by Kim in that both ends of the thin-walled sections remained attached to the parent material. This research can help to establish the threshold at which thin parts can be successfully machined while utilizing the cutting parameters just mentioned. Limitations in feasible

<sup>4</sup> *Ibid.*, 4.

cutting thicknesses were determined by comparing the data sets – measurements taken from each of the thin-walled sections – of the five different materials. ANOVA tests was performed in order to determine if there were statistically significant difference between the thin-walled sections cut from five different commonly used metals. The data was analyzed to show the effects of both material type and cutting parameters when machining thin-walled sections. A Sodick AQ325L wire-EDM machine, shown in Figure 1.1, was used to perform the experiment.

**Figure 1.1** - Sodick AQ325L wire-EDM Machine<sup>5</sup>

<sup>5</sup>Ibid., 3.

## **1.2 Hypothesis**

The null hypothesis for this study asserts that there is no significant difference of wire-EDM cutting performance of thin-walled sections in five different commonly used metals while utilizing a variation of the rough and finishing parameters.

## **1.3 Delimitations**

The object of this study was not to fully determine the cutting capabilities of the wire-EDM process or to determine the optimum cutting parameters and settings for a given wire-EDM machine. The machine settings were limited to the machine's default settings for the different materials, roughing passes, and finishing passes required to perform this study. The study was further limited to the use of 0.25 millimeter (0.010 inch) diameter brass wire, which has previously been specified. Six different web thicknesses were cut from five different types of materials. The largest web thicknesses represent those which were known to be achievable by current wire-EDM processes. These were used as a control, and smaller thicknesses were cut in order to provide observable data. Web thicknesses were not cut thinner than 0.05 millimeters (0.002 inches). The conclusions of this study are limited to the specific material types at their given Rockwell hardness.

## **1.4 Definition of Terms**

Accuracy – The degree of conformity to a specification.

Alternating Current (AC) – An electrical current that flows in one direction and then reverses and flows in the opposite direction.

Ampere – The rate of flow of electrons in an electrical circuit. One ampere is equal to 6.24 billion ( $6.24 \times 10^{18}$ ) electrons passing a given point in one second.

Anode – A positively charged electrode.

Arch – The flow of electricity across the gap between the electrode and the workpiece.

Cathode – A negatively charged electrode.

Contamination – The particles and debris found in the dielectric fluid.

CNC – Computer Numerical Control

$C_p$  – A measure of potential process capability. It is the ratio of the six-sigma spread of a process distribution to the tolerance of that distribution.

$C_{pk}$  – A measure of the actual process capability. It is calculated by dividing the distance of the process mean to the nearest tolerance limit by 3 standard deviations of the process.

CTE – Coefficient of Thermal Expansion

Deionize – To have the dielectric fluid return to a non-conductor of electricity or to remove an electrically conductive substance from water to make the water a dielectric fluid.

Deionized Water – Water that has been processed through a resin bed to remove the electrically conductive substances.

Dielectric Fluid – A liquid of low conductivity, which is used to control the spark gap, control the temperature of the workpiece, cool and solidify particles, and to flush out the kerf.

Dielectric Strength – The electrical rating of a dielectric fluid that determines the point at which it changes from an electrical insulator into an electrical conductor.

Normally specified as volts per mil.

Direct Current (DC) – An electrical current that constantly flows in one direction.

Discharge – The flow of electricity in the form of a spark.

EDM – Electrical Discharge Machining

Electrode – Electrically conductive tool used to carry the current to the workpiece.

Electrode Wear – The amount of electrode material consumed during the EDM process.

Electron – A negatively charged particle that orbits around the nucleus of an atom.

Filter – The component or assembly used to remove EDM chips and byproducts from the dielectric fluid.

Frequency – The number of sparks per second as determined by the spark-ON time and the spark-OFF time.

Heat-Affected Zone – The depth that the heat of the sparking has changed the characteristics of the original workpiece material.

Insulator – A material or substance that is a poor conductor of electricity.

Ion - An electrically charged atom which is formed by the loss or gain of an electron.

Ionization – The point at which the dielectric fluid changes from an insulator to a conductor of the electric current.

Kerf – A groove or notch made by a cutting tool by the removal of material from a workpiece.

Machining Voltage – The voltage between the electrode and the workpiece during sparking.

Material Removal Rate – The volume of workpiece that is removed in a given unit of time. Usually measured in cubic inches per hour.

OFF Time – Time between sparks as set by the power-supply control.

Ohm – The unit used to describe the resistance of an electrical current to the flow of an electric current.

ON Time – Time when the spark's electric current may flow as set by the power-supply control.

Parent Material – The material unaffected by the EDM-spark-energy temperatures.

Precision – The consistency of results in repeated experiments.

Pulse Generator – Part of the EDM machine that creates a surge of electrical current.

P-value – A measure of probability showing how likely it is that the results of an experiment have occurred randomly.

Recast Layer – The workpiece-EDM surface that consists of material that is vaporized by the spark and re-deposited onto the workpiece also including the workpiece material that is melted by the spark.

Sinter – To form a coherent mass by heating without melting.

Start Hole – Predrilled opening in the workpiece that provides a location to thread the wire.

Spark – The controlled electric discharge between an electrode and workpiece through an ionized dielectric fluid.

Spark Gap – The distance between the electrode and workpiece during sparking with the dielectric fluid in an ionized condition.

Speed – The advance rate of the workpiece perpendicular to the wire. Usually measured in inches per minute.

Sublimes – When a solid goes directly to a gas without melting or going through a liquid state.

Surface Finish – The EDM-machined surface produced by sparking.

Thermal Conductivity – For steady-state heat flow, the proportionality constant between the heat flux and the temperature gradient. Also, a parameter characterizing the ability of a material to conduct heat.

Tolerance – The permissible deviation from an ideal.

Vaporize – To cause to change to vapor. With EDM this often occurs through sublimation.

White Layer – A surface condition caused by the rapid quenching of vaporized and melted ferrous material in the dielectric fluid. This material has a high carbon content and becomes martensite. This martensite appears as a white layer during metallurgical inspection.

Workpiece – The material being formed into a part.

## 2 Background and Review of Literature

### 2.1 Introduction

In order to help further the utilization, capabilities, and applications of wire Electric Discharge Machining (wire-EDM) throughout the manufacturing sector, this study explored the feasibility of wire-EDM in cutting small, thin-walled sections from five different commonly used metals. Relative to the majority of other machining processes, wire-EDM is a comparatively new process. Due to its method of material removal, it has often been considered a non-traditional machining process.

Expanding from its initially small niche of precision tooling manufacturing, its broad capabilities have allowed it to expand its influence to encompass production, aerospace/aircraft, medical, and virtually all areas of conductive material machining. Further augmented by automatic tool changers, automatic threading, slug removers, robotic workpiece changers, and palletization, this fascinating manufacturing process has attained almost virtual machining autonomy and has rightfully taken its place alongside the more conventional machining processes of lathes, mills, and grinders as self-supporting profit centers.<sup>6</sup>

In order to understand and study the capabilities and limitations of the wire-EDM process, one needs a basic knowledge of that process and an understanding of the machining parameters that affect the products being manufactured. A review of literature was begun by reading articles and books which provide an overview of the process, the specific components of the machine, and the parameters by which the machine functions. Some of these include *The EDM Handbook* by E. Bud Guitrau, and *Complete EDM*

---

<sup>6</sup> Bud Guitrau, *The EDM Handbook* (Cincinnati, OH: Hanser Gardner Publications, 1997) 3.

*Handbook* by Carl Sommer and Steve Sommer. After gaining a base of knowledge, specific articles and studies, which focus to a greater degree and depth on the key components and issues, were reviewed. A thesis written by Sangseop Kim, *Determination of Wall Thickness and Height Limits when Cutting Various Materials with Wire Electric Discharge Machining Process* served as a major resource for this study.

Utilizing the knowledge that I gained from this review of literature, an overview of the wire-EDM machine, its components, and machining parameters is set forth and can be seen hereafter. The subjects that will be discussed are the wire-EDM process, which includes the EDM wire, electrical discharge power units, dielectric fluid, filtration, machine movements; surface characteristics which include surface finish, thermal effect, corrosion effect, electrolysis effect; cutting speed; and accuracy. These components and parameters were important to understand given that their proper selection and use play a vital role in the cutting capabilities of the wire-EDM process.

The research conducted for this thesis is based on work done by Sangseop Kim, the difference being the degree to which the sections were constrained during the machining process. In this study, each of the thin-walled sections remained attached to the parent material on both ends while in the research performed by Kim the thin-walled sections only remained attached to the parent material on one end.

## **2.2 Wire-EDM Process**

Electrical Discharge Machining (EDM) is a nontraditional machining process utilized to machine electrically conductive materials. Sparks which jump between an electrode and the workpiece are precisely controlled in order to successively cut a

programmed path through the workpiece. One of the fundamentals “of the process is that only one spark occurs at any instant. Sparking occurs in a frequency range from 2,000 to 500,000 sparks per second causing it to appear that many sparks are occurring simultaneously.”<sup>7</sup> Each spark vaporizes part of both the electrode and the workpiece thus increasing the distance between them at that point. As a result, the subsequent spark occurs at another location where the electrode and the workpiece are closest. This progression of sequential sparks is shown in Figure 2.1 which depicts the plunge-EDM process.

**Figure 2.1** – Diagram of Sequential Sparks

<sup>7</sup> Elman Jameson, *Electrical Discharge Machining* (Dearborn, Michigan: Society of Manufacturing Engineers, 2001) 1.

With regards to spark progression, wire-EDM and plunge-EDM function in exactly the same manner. A diagram of the plunge-EDM process is shown because it is easier to visualize and depict spark progression through this process.

In all EDM processes, a dielectric fluid is used to help control the spark gap between the electrode and the workpiece, to flush away eroded material, and to control the temperature of the workpiece and its surroundings.

The EDM process is being utilized in many tooling applications and “has found a home in the manufacturing of production parts, especially small parts less than one half inches square with thickness in the range of [0.127 to 2.032 millimeters (0.005 to 0.08 inches)] in wall thickness.”<sup>8</sup> EDM is also used to produce punch and stamping dies for the automotive industry that can reach sizes of 100,000 pounds.<sup>9</sup> One of the most significant advantages of EDM is that it can machine any conductive material regardless of that material’s hardness. Consequently, EDM has become the machining process of choice for cutting materials such as Poly Crystalline Diamond and Tungsten Carbide.

In wire-EDM the electrode is a wire. These wires can range in diameter from 0.03 to 0.3 millimeters (0.001 to 0.012 inches).<sup>10</sup> The wire is unwound from a spool at the top of the machine and travels vertically down through the workpiece, after which the spent wire is collected. Due to its reduction in diameter, as a result of the machining process,

the wire can be used only once. Figure 2.2, a diagram representing a wire-EDM, shows the travel direction of the wire along with the general motions relatively possible by the wire and the workpiece.

**Figure 2.2** - Diagram of a Wire Fed through a Workpiece, and their Relative Motions<sup>11</sup>

<sup>11</sup> Carl Sommer and Steve Sommer, *Complete EDM Handbook* (Houston, TX: Advance Publishing, Inc., 2005), 30.

### 2.2.1 EDM Wire

Even though the EDM wire never makes contact with the material being machined, it is considered the tool of the wire-EDM machine. The wire is continually being fed vertically through the workpiece while the workpiece is moved along a horizontal plane. The resultant motion along this horizontal plane cuts a slot through the workpiece that is slightly larger than the diameter of the wire. The wire is typically perpendicular to the surface of the workpiece, except when tapers are being machined, in which case the wire can pass through the material at an angle of up to 30 degrees.<sup>12</sup>

According to Intech EDM, “The ideal wire electrode material for [the wire-EDM] process has three important criteria: high electrical conductivity; sufficient mechanical strength; and optimum spark and flushing characteristics.”<sup>13</sup>

The electrical conductivity of the wire is important inasmuch as the heat of each spark is determined by the amount of current that passes through the wire and across the spark gap. This causes more material to be vaporized per spark and thus achieves faster cutting speeds.

In order to maintain a straight cut in the direction the wire travels, the wire is placed under tension by the wire-EDM machine. This force also reduces the amount of vibration in the wire and deflection due to the flow of the dielectric fluid around the wire. The mechanical strength of the wire needs to be sufficient to withstand these forces even after its diameter has been reduced by the machining process.

---

<sup>12</sup> EDM Technology Transfer, “Fundamentals of EDM,” available from <http://www.edmtt.com/techpapers/characteredm/charedm.html#abstract1>; Internet; Wire-cut EDM: Principals of Operation.

<sup>13</sup> Intech EDM, “A Reference to Understanding, Selecting and Using Wire on Wire-cut EDM Machines,” available from <http://www.intech-edm.com/newsroom/documents/wirebook.pdf>; Internet; accessed 6 March 2006, 2.

The material properties of the wire are one of the major factors that help to optimize the spark and flushing through the kerf.

It is highly desirable for the wire to erode, or wear, because the vaporized wire material aids in the formation of subsequent spark ionization channels. In addition, a higher degree of vaporization into microscopic particles, rather than melting, greatly improves the efficiency of the flushing process and, by suppressing arcing, the stability of the cut.<sup>14</sup>

Different materials have been utilized in order to provide situation specific solutions to these needs. The factors that help to determine these different solutions are the EDM machine, workpiece thickness, final tolerances, desired finish, size of the inside radii, taper angles, and the workpiece material.<sup>15</sup>

The first material used in the production of EDM wire was copper. As the power supplies and controllers for the wire-EDM became more sophisticated, they exceeded the capabilities of the pure copper wire. Developers subsequently experimented with the use of brass in order to meet the new demands. Brass is an alloy of copper and zinc, typically alloyed at 63-65% Cu and 35-37% Zn. “The addition of zinc provides significantly higher tensile strength, a lower melting point and higher vapor pressure rating, which more than offsets the relative losses in conductivity.”<sup>16</sup> Once the EDM industry started pushing the cutting capabilities of brass wires, manufacturers developed coated wires. Zinc is very desirable in EDM wire because of its vaporization temperature, but brass wires cannot efficiently be produced with higher percentages of zinc than those that have been listed above. In order to obtain the desired properties that are provided by zinc while maintaining sufficient levels of tensile strength and conductivity, a brass or copper

---

<sup>14</sup> Ibid., 2.

<sup>15</sup> Ibid., 4.

<sup>16</sup> Ibid., 3.

wire core is coated with zinc. This further enhanced the properties of spark formation and flushing over the brass wire. Fine wires of molybdenum and tungsten have been developed for highly specialized situations, and therefore, a discussion of these would be beyond the scope of this research.

Even though coated wire is appropriate for 95% of the jobs currently being run and has been proven to outperform brass wire, brass wire is still the product of choice for the majority of EDM shops.<sup>17</sup> Due to this trend in industry, I used Intech SuperBrass 900 for this study. It has a  $\text{Ø } 0.25 \text{ mm}$  ( $\text{Ø } 0.010 \text{ in}$ ), Cu 63% and Zn 37%, 1% elongation, and  $900 \text{ N/mm}^2$  tensile strength.<sup>18</sup>

### **2.2.2 Electrical Discharge Power Units**

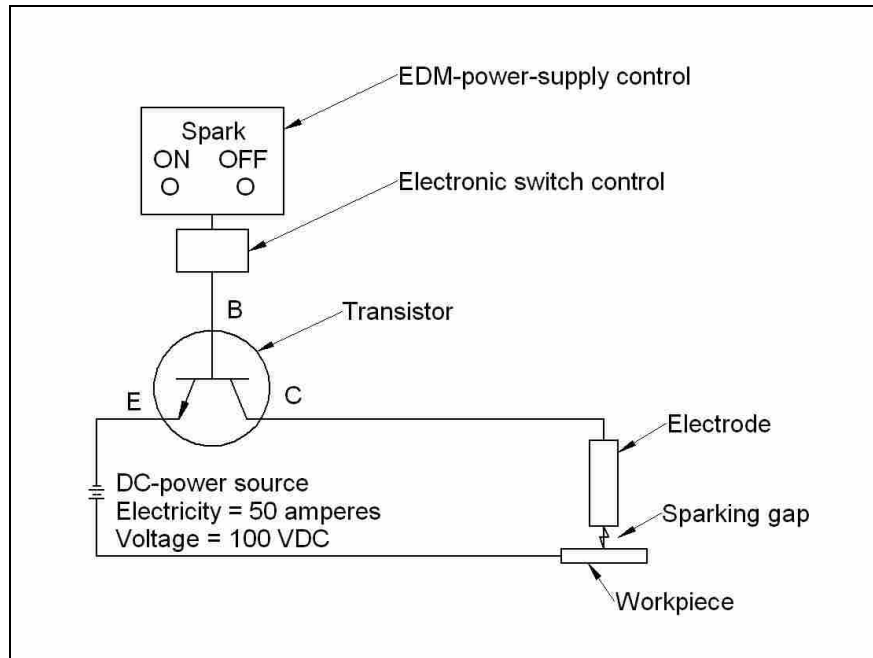

The electrical discharge power unit is the system that controls the electricity so that it is delivered to the electrode in the appropriate amounts and at the correct time. “Wire discharge machines, for example, generate extremely short pulsed currents at steady repetitive intervals by using a current generating power unit and controlling the current into pulse forms.<sup>19</sup> The system executes this function by controlling the on-time, the off-time, and the amperage that is run through the electrode. A single cycle of the EDM process is the combination of the on-time and the off-time. This time is measured in microseconds ( $\mu\text{sec}$ ). A basic representation of the electrical circuit is shown in Figure 2.3.

---

<sup>17</sup> Ibid., 5.

<sup>18</sup> Intech EDM, “Wire,” available from <http://www.intech-edm.com/pdf/WCwire.pdf>; Internet; accessed 6 March 2006, 2-9

**Figure 2.3** - Basic Electrical Circuit<sup>20</sup>

The on-time is defined as the time when the current is turned on. During this time several things are happening. The voltage increases until it has a sufficient amount of energy to align the few ions and microscopic particles in the dielectric fluid and jump the spark gap between the electrode and the workpiece. Once the spark connects the two pieces the voltage decreases and the amperage increases. The material that is in direct contact with the spark is vaporized, and a gas bubble is created around the spark. At some point, enough of the spark energy is used so that vaporization ceases and melting begins. At this point, power is turned off thus beginning the off-time. The bubble that formed around the spark now implodes, pulling most of the molten metal out of the crater created by the spark. Dielectric fluid rushes in and cools the affected areas. The compromised dielectric fluid and the debris are flushed out of the kerf allowing the

<sup>20</sup> Elman Jameson, *Electrical Discharge Machining* (Dearborn, Michigan: Society of Manufacturing Engineers, 2001) 124.

process to begin again.<sup>21</sup> Diagrams of the spark sequence briefly described above are shown in Figure 2.4.

### 2.2.3 Dielectric Fluid

There are typically two different dielectric fluids that may be used in an EDM process. The vast majority of wire-EDM machines use deionized water for the dielectric fluid. Oil, which is normally used as a dielectric fluid in vertical or plunge EDM and occasionally in special cases with wire-EDM, is the other alternative. “However, this countermeasure, [dielectric oil], causes microfissures, because the oil does not cool down the part surface as quickly as water does. Microscopic cracks result.”<sup>22</sup> For this reason, deionized water has almost totally replaced oil as the dielectric fluid of choice for wire-EDM.

EDM dielectric fluids perform four functions necessary for spark machining. The fluids provide

1. a known electrical barrier between the electrode and workpiece;
2. cooling for the electrode and workpiece;
3. cooling for the vaporized material that becomes the EDM chip upon solidification; and
4. a means for removal of the EDM-spark debris from the spark gap.<sup>23</sup>

In order to use water as a dielectric fluid, all of the ions have to be removed from the fluid through a chemical process leaving pure H<sub>2</sub>O. This process reduces the electrical conductivity of the water and thus creates a substance which can be utilized in helping to control the gap distance between the wire and the material being cut, through its creation

<sup>23</sup> Elman Jameson, *Electrical Discharge Machining* (Dearborn, Michigan: Society of Manufacturing Engineers, 2001) 154.

Item a - “Open-gap voltage. The electrode is seeking the workpiece while “cutting air.” Graph shows high potential voltage only, and no current. Time-line runs horizontally.

Item b - Displays the electromagnetic field created between electrode and workpiece. Dielectric within this field becomes polarized as resistance decreases. Voltage levels off.

Item c - “On-time” begins. Dielectric resistance is overcome and spark occurs, generating current which vaporized the workpiece. As amperage increases, voltage will decrease.

Item d - Spark is plasma hot and enclosed within a sheath of gases. Vaporization of workpiece continues.

Item e - Gas bubble continues to expand rapidly (vapor pressure). At a certain point, vaporization will cease and melting begins. Dielectric contamination increases.

Item f - Amperage and voltage have leveled off as contamination and thermal damage of dielectric increases. Dielectric is now severely compromised and its electrical resistivity continues to rise. If allowed to continue, conditions will cause “dc arcing” or a wire break.

Item g - Power is interrupted during “off-time” part of the EDM cycle. Current drops to zero. Gas bubble collapses upon removal of heat source.

Item h - Gases and contaminated dielectric will naturally disperse, but providing forced or “sealed” flushing is best and will significantly reduce dielectric recovery time and increase cutting speed.

Item i - Contaminants and damaged dielectric are expelled, revealing EDM crater on workpiece and wear on electrode. Dielectric begins reionization, allowing repeat of cycle.

**Figure 2.4** - Diagrams of the Spark Sequence<sup>24</sup>

<sup>24</sup> Bud Guitrau, *The EDM Handbook* (Cincinnati, OH: Hanser Gardner Publications, 1997) 20-21.

of an electrical barrier. This property is referred to as dielectric strength – “a measure of the insulating capacity of a given fluid in an EDM environment. Higher dielectric strength helps minimize DC arcing and is frequently touted as an indicator of overall EDM performance.”<sup>25</sup>

Because the dielectric fluid is compromised due to contamination and the creation of ions which results from the EDM process fresh dielectric fluid needs to be introduced into the cutting environment. “Flushing is the process of introducing clean dielectric fluid into and through the spark gap. This serves several purposes. Flushing

1. introduces ‘fresh’ dielectric to the cut for reionization,
2. flushes away the ‘chips’ and debris from the spark gap, and
3. cools the electrode (or wire) and workpiece.”<sup>26</sup>

Without sufficient flushing the cutting speed of the machine would be reduced, and in extreme cases, the machine would cease to function due to DC arcing. Flushing helps the dielectric fluid perform these functions.

#### **2.2.4 Filtration**

In order to maintain the quality of the dielectric fluid, wire-EDM utilizes two different filtration processes: 1) mechanical filtration, which filters out the particles that have contaminated the dielectric fluid; 2) chemical filtration, which removes the ions from the dielectric fluid which were created through the EDM process.

---

<sup>25</sup> Intech EDM, “A Guide to Understanding and Selecting EDM Dielectric Fluids,” available from <http://www.intech-edm.com/newsroom/documents/dieloil.pdf>; Internet; accessed 6 March 2006.

<sup>26</sup> Bud Guitrau, *The EDM Handbook* (Cincinnati, OH: Hanser Gardner Publications, 1997) 161-162.

When a spark is discharged between the electrode and the workpiece, it vaporizes some of the material from both the electrode and the workpiece. At the end of the on-time cycle some material is also melted. This molten material solidifies and is flushed away by the dielectric fluid. Before the dielectric fluid can be reused, these contaminants need to be removed through a filtration process. Disposable paper filters are the most common form of mechanical filtration used in wire-EDM. The water is pumped through these filters which typically have a filtration range of 5 to 25 microns.<sup>27</sup> These filters need to be replaced periodically depending on their size, the usage of the machine, and the types of material being cut.

Other common mechanical filtration systems are permanent paper media, plastic cartridge filters, diatomaceous earth filters, electrostatic filtration, and centrifuge. These systems can be implemented for individual machines, or they can be installed as a central filtration system for many machines in one shop.<sup>28</sup>

Because of the different components found in alloyed materials and the impurities found in all material, ions are created in the dielectric fluid due to the thermal reaction that occurs during the machining process. An ion is an electrically charged atom which is formed by the loss or gain of an electron. These ions exist as either positively charged cations or negatively charged anions. In order to maintain the nonconductive property of the dielectric fluid, these ions need to be removed.

Table 2.1 lists some of the common ions found in tap water. Several of these same ions are dissolved into the water when the spark from the EDM process vaporizes

---

<sup>27</sup> Bud Guitrau, *The EDM Handbook* (Cincinnati, OH: Hanser Gardner Publications, 1997) 174.

<sup>28</sup> *Ibid.*, 174-176.

Ferrous	Phosphate

and melts the electrode and the workpiece. Mixed-bed resins are used in order to remove these dissolved solids from the dielectric fluid.

“The resin bed is made up of a mixture of positively charged (cation) and negatively charged (anion) polystyrene plastic beads; which is why it is referred to as a ‘mixed-bed resin’.”<sup>30</sup> Figure 2.5 is a picture of a mixed bed resin. The dielectric fluid is

**Figure 2.5** - Mixed Bed Resin<sup>31</sup>

---

<sup>29</sup> Ibid., 178.

<sup>30</sup> Intech EDM, “Wire-cut D.I. Resin: Understanding D.I. Resin, and Four Engineered Solutions,” *Sparks*, (Spring 2000): 1.

<sup>31</sup> Res-Kem Corp., “Resin,” available from <http://www.reskem.com/pages/resin.php>; Internet; accessed 30 October 2006.

forced through a container filled with the mixed-bed resin. Due to the charges of the ions in the dielectric fluid, they react with the charged beads in the resin and are thus extracted from the dielectric fluid.

The beads themselves are highly porous, and most of the ion exchange process takes place throughout the structure of the bead, not just on the surface. This is the reason that the [deionization] process takes place *after* the water has been filtered; otherwise the bead surfaces would become clogged or coated, and they would lose much of their capacity.<sup>32</sup>

This process restores the insulating property of the dielectric fluid making it possible for the fluid to be reused.

Another important component of the filtration system is a chiller which maintains the temperature of the dielectric fluid. Heat is transferred to the dielectric fluid from the energy released during the cutting process. Although the sparks can reach temperatures ranging from 8,000 to 12,000°C (14,432 to 21,632°F),<sup>33</sup> the pumps that move this fluid through the system serve as the main heat contributors to the dielectric fluid. Modern machines have flushing pressures that can reach 300 psi. The heat generated from the motors and pumps is transferred to the dielectric fluid as it passes through the system.

A large share of part accuracy (besides the capability to cool the machine) is the result of maintaining uniform machine component, tooling, and part temperatures in relation to the temperature of the room. Temperature changes during cutting can cause the part to bend, twist, or distort in addition to ‘growing’ or elongating due to the coefficient of expansion for a given material.<sup>34</sup>

Therefore, in order to maintain the desired part accuracies a chiller is an essential component of a wire-EDM machine.

<sup>34</sup> Ibid., 179.

### 2.2.5 Machine Movements

Several components are necessary for the EDM machine to follow a programmed path in order to create a specific part. In comparing the different systems of an EDM machine to the human body, there are muscles, the brain, and the nerves. Respectively these systems translate to the linear motors, the Computerized Numerical Control (CNC) system, and the motion controllers.

Servo systems are utilized in the older EDM machines, in vertical or plunge EDM machines, and in the vertical axis of some of the newer wire-EDM machines, but the majority of the servo systems in wire-EDM machines have been replaced by linear motors. Linear motors are superior to rotating motors in traveling speed and positional accuracy. These motors can move with accuracy in increments of 1 micrometer.<sup>35</sup> The linear motors and/or servo systems are the muscles of an EDM machine enabling it to move along the programmed path.

The CNC system is the brain of the EDM machine. It controls the motions of the EDM machine. The CNC system follows the inputs given to it through a program which tells the machine what functions it needs to perform and where it needs to move. Modern CNC units are “capable of controlling up to eight axes simultaneously.”<sup>36</sup>

The motion controllers or “nerves” of an EDM machine work in conjunction with the CNC system and the linear motors. They “control the high-speed and high-precision

---

<sup>35</sup> Sodick Co., Ltd, “Linear Motors,” available from <http://sodick.jp/tech/linear.html>; Internet; Accessed 11 April 2006.

<sup>36</sup> Sodick Co., Ltd, “CNC Units,” available from <http://sodick.jp/tech/nc.html>; Internet; Accessed 11 April 2006.

motions of [the] linear motors based on commands from the CNC units.”<sup>37</sup> The motion controllers tell the machine where it is in comparison to the electrode. The entire system works on the principal of the Cartesian Coordinate System. Every point within the work envelope of the machine can be defined and located thus enabling the machine to follow a given path allowing it to cut the programmed part.

“With the advent of ever-improving electronic circuitry, advanced motion techniques, computer numeric controls (CNC) and other modern controlling mechanism’s, EDM machine tools have become extremely reliable, accurate and dependable.”<sup>38</sup>

## **2.3 Surface Characteristics**

The surface of a part machined by wire-EDM can be discussed on two different levels, surface finish and surface integrity. Although the two subjects are related they warrant individual attention and discussion of their causation.

### **2.3.1 Surface Finish**

The surface finish refers to the smoothness of the part surface machined by a given process. Unfortunately, no standard has been universally accepted for measuring the surface finish of parts. Table 2.2 lists several of the different methods for calculating the numerical representation of the surface finish and the typical units used to define the measurements. The representation closest to a standard utilized in the United States is the Roughness Average ( $R_a$ ). This is defined as “the arithmetic average of all departures

---

<sup>37</sup> Sodick Co., Ltd, “Motion Controllers,” available from <http://sodick.jp/tech/smc.html>; Internet; Accessed 11 April 2006.

<sup>38</sup> The Damm Company, Inc., “What is EDM?” available from <http://www.thedammcompany.com/whatisedm.html>; Internet; Accessed 11 March 2006.

**Table 2.2** - Commonly Used Surface Finish Measurements

<b>Scale</b>	<b>Definition</b>	<b>Unit*</b>
RMS	Root Mean Square	μin.
AA	Arithmetic Mean (average)	μin. or μm
R <sub>a</sub>	Roughness Average	μin. or μm
H <sub>max</sub>	Maximum Roughness Depth	μin. or μm
R <sub>max</sub>	Maximum Roughness Depth	μin. or μm

\* 1 μin. = 1/1,000,000 inches or 0.025 μm

1 μm = 1/1,000,000 meter or 40 μin.

of the roughness profile from the centerline of the evaluation length. It is also known as the arithmetic average (AA) and the centerline average (CLA).”<sup>39</sup> “The finest surface finishes will be of the order of R<sub>a</sub> 0.10 [μm], and the visual effect is almost like a mirror finish.”<sup>40</sup>

Researchers cite several factors that affect the surface finish of a part machined by wire-EDM, namely: discharge current, discharge capacitance, pulse duration, pulse frequency, wire speed, wire tension, average working voltage, dielectric flushing pressure, conductivity of dielectric fluid, current-limiting resistance, pulse generating circuit, table speed, and gap distance. All of the various researchers performed finishing passes in their experiments while adjusting some of the parameters listed above. Because each of the researchers was focusing on different variables of the finishing process, their conclusions are not totally consistent; however, there is fairly consistent agreement that the voltage and pulse on-time are the two leading determinants of the surface finish. One other factor that warrants discussion is the type of pulse-generating circuit used in the

---

<sup>39</sup> Ibid.

<sup>40</sup> Charnilles US, Corporate Publications, “Principle,” available from <http://www.charmillesus.com/products/whatsedm/principle.cfm>; Internet; accessed 6 March 2006.

machining process.<sup>41, 42, 43</sup> By varying the voltage and pulse on-time in the appropriate manner, a finer surface finish can be achieved. This is the basic definition of finishing passes and how they are achieved. In discussing roughing and finishing passes hereafter we will examine in more detail the effects that voltage and pulse on-time have on the surface finish and it's characteristics.

In order to cut materials as quickly as possible during the roughing pass, high voltage and long on-time settings are utilized. The longer on-time and higher voltage equate to more thermal energy in the spark thus vaporizing and melting more of the workpiece material. This results in larger craters left in the surface of the workpiece, and a thicker recast layer and heat affected zone. Figure 2.6 shows magnified pictures of the

**Figure 2.6** - Magnified Pictures of Craters Created by Single Sparks<sup>44</sup>

---

<sup>41</sup> N. Tosun et al., eds., “The Effect of Cutting Parameters on Workpiece Surface Roughness in Wire EDM,” *Machining Science and Technology*, 7, no. 2 (2003): 217.

<sup>43</sup> J. Huang et al., eds., “Determination of finish-cutting operation number and machining-parameters setting in wire electrical discharge machining,” *Journal of Materials Processing Technology*, 87, no.1-3 (1999): 80.

<sup>44</sup> Michel Frank et al., eds., “EDM for Micro Fabrication – Technology and Applications,” available from [http://www.public.iastate.edu/~weichiat/527/EDM\\_Microfab.pdf](http://www.public.iastate.edu/~weichiat/527/EDM_Microfab.pdf); Internet; accessed 6 March 2006, 3.

craters created by single sparks from the EDM process. At the bottom of each picture is a scale which gives the size of the individual craters. It should be noted that the sizes of the craters is effected by the amount of current that is allowed to pass through each of the sparks, and therefore these pictures are only a representation of approximate size and shape.

Finishing passes are utilized to remove the recast layer, the heat affected zone, and the rougher surface finish left by the roughing pass. Figure 2.7 shows magnified pictures of the surface finishes which can be obtained through the use of roughing and finishing passes. The roughness average for each of the surfaces is given, and each of the pictures show a scale of 10  $\mu\text{m}$ .

**Figure 2.7** - Magnified Pictures of Surface Finish<sup>45</sup>

In order to enhance the effects of the finishing passes and obtain a smoother surface finish, the voltage is dropped and the on-time is reduced. Because of the drop in voltage, the wire is moved closer to the workpiece thus reducing the gap which allows smaller sparks to be generated at a greater frequency. The wire will follow a similar path to that which it traveled in the roughing cut around the workpiece. This process can be

---

<sup>45</sup> J. Huang et al., eds., “Determination of finish-cutting operation number and machining-parameters setting in wire electrical discharge machining,” *Journal of Materials Processing Technology*, 87, no.1-3 (1999): 77.

repeated successively creating finer surface finishes each time. With the appropriate settings of the different parameters a surface finish of  $R_a = 0.22 \mu\text{m}$  can be achieved.<sup>46</sup>

Figure 2.8 is a schematic showing the decrease in surface roughness due to finishing passes.

**Figure 2.8** - Decrease in Surface Roughness due to Finishing Passes

The pulse-generator can also have a slight effect on surface finish. Typically, pulse-generators for wire-EDM machines can be utilized in three different ways: DC arching with the wire being the anode and the workpiece being the cathode, DC arching with the wire being the cathode and the workpiece being the anode, and AC arching

---

<sup>46</sup> Y. Liao et al., eds., "A study to achieve a fine surface finish in Wire-EDM," *Journal of Materials Processing Technology*, 149, no. 1-3 (2004): 166.

where the wire and workpiece alternate between anode and cathode. A spark will typically jump from the positively charged anode to the negatively charged cathode. It has been observed that there is a greater amount of material removed from the cathode. By properly defining the direction the sparks will jump, an operator can successfully decrease the roughness of the surface finish. At times, other more significant parameters will override this principal.

**2.3.2 Thermal Effect**

After a part has been cut by EDM, there are basically three resultant layers of material with varying characteristics. These layers starting from the surface are the recast layer, the heat affected zone, and the parent material. Figure 2.9 is a diagram depicting these different layers. The recast layer is part of the parent material that has been melted, and

**Figure 2.9** - Thermally Affected Zone

has then re-solidified on the surface of the part. The heat affected zone is a layer of the parent material which has been affected by the heat generated during the machining process. In both of these layers the crystalline structure of the parent material has been affected and/or changed. Sometimes, the chemical composition of the recast layer may also be altered.

As discussed in earlier sections, the thickness of the outer two layers will vary depending on the voltage and on-time settings of the EDM machine. When the machine settings for rough cutting are used the thickness of the outer two layers can approach 0.76 mm (0.030 in.). This thickness can be dramatically reduced to approximately 0.05 mm (0.002 in.) when finishing settings are utilized.<sup>47</sup> Figure 2.10 shows magnified pictures of the recast layer which can be obtained through roughing and finishing passes. The pictures are oriented such that you are looking vertically down the cut surface so that the thickness of the recast layer can be observed. A thickness of less than 3  $\mu\text{m}$  was achieved by the 2<sup>nd</sup> finishing pass.

**Figure 2.10** - Magnified Pictures of the Recast Layer<sup>48</sup>

<sup>48</sup> J. Huang et al., eds., "Determination of finish-cutting operation number and machining-parameters setting in wire electrical discharge machining," *Journal of Materials Processing Technology*, 87, no.1-3 (1999): 77.

Because of the heat differential between the dielectric fluid and a recently created spark cavity, internal stresses in the workpiece can be created. These stresses can create micro-cracks in the surface of the workpiece. Due to the mechanical stresses applied to a tool, manufactured by the EDM process, during its utilization, these micro-cracks can propagate into the parent material causing the tool to crack and fail. As a result, for most high impact tools, the recast layer, which is very hard, brittle, and highly stressed, may need to be removed entirely in order to prevent failure of the tool.<sup>49</sup> Subsequent processes utilizing other machines are used in order to achieve this goal.

### **2.3.3 Corrosion Effect**

Because the dielectric fluid of choice for wire-EDM is deionized water, other factors are introduced into the EDM process. Water is the universal solvent, and therefore will start to dissolve whatever it comes in contact with. “On steel workpieces, [where deionized water is used as the dielectric fluid] corrosion increases, the surface is weakened, and rusting accelerates.”<sup>50</sup> Even though the deionized water has these effects, the advantages it creates still outweigh its negative effects.

### **2.3.4 Electrolysis Effect**

It is impossible for any purification system to remove all of the ions from the water being used as the dielectric fluid. A very small portion of the H<sub>2</sub>O molecules will naturally split into H<sup>+</sup> and OH<sup>-</sup> ions. Due to this phenomenon, electrolysis sometimes

---

<sup>49</sup> Ibid., 257-259.

<sup>50</sup> Jean Dewarrat, “Eliminating EDM Electrolysis Electrically,” *Cutting Tool Engineering*, 46, no. 3 (April 1994): 38.

becomes a problem when using deionized water as a dielectric fluid. Electrolysis is a chemical reaction that will deposit or remove material from an electrode through the utilization of an electrical current. “The problem has become even more widespread due to the increased use of sintered materials, such as tungsten carbide, which are extremely sensitive to the effects of electrolysis.”<sup>51</sup> Because the workpiece has an electric charge it attracts the anions or cations in the dielectric fluid, deionized water. These ions bombard the surface of the workpiece. In the case of tungsten carbide, the ions attack the cobalt binder which is used to sinter the tungsten carbide thus weakening the surface and corners of the resultant tool. Studies have been performed to research different methods of reducing electrolysis. One alternative is to use AC power, thus decreasing the degree to which the surface of the part is bombarded by the ions in the dielectric fluid.<sup>52</sup> Another study was performed in which high-performance spark generators were used to emit high-voltage pulses that caused the ions in the dielectric fluid to oscillate thus practically eliminating their migration towards the workpiece. This almost eliminated the bombardment of ions on the surface of the workpiece.<sup>53</sup>

## **2.4 Cutting Speed**

Cutting speeds for EDM machines are measured in square inches per hour (sq. in./hr) regardless of the type of machine. The advances in technology and machine

---

<sup>53</sup> Jean Dewarrat, “Eliminating EDM Electrolysis Electrically,” *Cutting Tool Engineering*, 46, no. 3 (April 1994): 40.

capabilities over the years have enabled increased cutting speeds in EDM. Cutting speeds are not only influenced by the age and type of machine, but also by the properties and characteristics of the workpiece being cut. The workpiece melting temperature and its electrical conductivity are the two greatest factors relative to the workpiece that affect the cutting speed. It needs to be noted that the cutting speeds which manufacturers publish for their different machines have been obtained under ideal cutting conditions. Manufacturers will typically use 57 mm (2 ¼ in.) D2 hardened tool steel with ideal flushing conditions in order to obtain a cutting speed for wire-EDM machines.<sup>54</sup> Currently, wire-EDM machines have the capability of cutting 30 sq. in./hr. in tool steels. Although this will provide a benchmark for comparison, it does not represent the cutting speeds of other materials. Due to the high conductivity and low melting temperatures of aluminum, some manufacturers have achieved cutting speeds exceeding 80 sq. in./hr.<sup>55</sup>

The machine settings set by the operator and programmer also affect the cutting speed. The settings which have the greatest impact on cutting speeds are the amount of amperage, the on-time, and flushing conditions. The greater the amount of amperage allowed to pass through the spark, the hotter the spark will be. Related to this is the on-time. Instead of increasing the amperage, the length of time the spark is allowed to exist will also increase cutting speeds. Both of these settings, when maximized, will vaporize a greater amount of material from the workpiece. It is possible to increase these settings to the point where an adverse effect occurs to both the cutting speed and the workpiece.

<sup>55</sup> Bud Guitrau, *The EDM Handbook* (Cincinnati, OH: Hanser Gardner Publications, 1997) 162.

If increased too much, the spark will destabilize and may cause the wire to rupture do to the increased heat.

Flushing helps stabilize the area around the electrode in order to maintain the required conditions for a subsequent spark to generate. If the damaged dielectric fluid and the contaminants are not flushed out of the kerf, the sparks will destabilize and DC arching will occur, thus reducing cutting speeds.

## 2.5 Accuracy

The Sodick AQ325L wire-EDM machine that was used to cut the parts for this thesis was also used by Joel Mundt for his thesis on *Wire Electric Discharge machining Performance with Multiple Finishing Passes*. Part of that study included the cutting of octagonal parts from 25.4 millimeter (1 inch) thick D2 Tool Steel that had been heat-treated to a hardness of RC 64.2.<sup>56</sup> Part of his thesis was to observe the accuracy of the wire-EDM machine by measuring the distance between opposite sides of these octagonal specimens and compare the results with the target values. Mundt concluded, for this part of his thesis, that the data showed a trend of increasing accuracy when going from one to three finishing passes. His observances are as follows

- A mean deviation of a negative .0088 millimeters (.00348 inches) with one finishing pass,
- A mean deviation of a positive .0038 millimeters (.000151 inches) with two finishing passes, and

---

<sup>56</sup> Mundt, Joel, *Wire Electric Discharge Machining Performance with Multiple Finishing Passes* (School of Technology, Brigham Young University, Thesis. April 2002), 22-23.

- A mean deviation of a positive .0011 millimeters (.000042 inches) with three finishing passes.<sup>57</sup>

This was used in comparison to the data obtained in this thesis in order to eliminate bias due to the accuracy of the wire-EDM machine.

Other important parameters which will also affect the accuracy of the wire-EDM machine are the settings which are used for the pulse generator and the tool offsets, which are used dependent on the number of finishing passes being run. It was that the default parameters for each of these settings were used in both of the previous theses by Mundt and Kim.

## 2.6 Related Research

Sangseop Kim performed some related research for his thesis, *Determination of Wall Thickness and Height Limits when Cutting Various Materials with Wire Electric Discharge Machining Process*, and thus laid the groundwork for further research in cutting thin-walled sections with a conventional wire-EDM machine. Kim stated that, “The purpose of [his] thesis study was to determine if there are significant differences in the height of the [thin-walled sections] when the thickness becomes smaller and when different materials are cut on the [wire-EDM] machine.”<sup>58</sup>

---

<sup>57</sup> Ibid., 77

<sup>58</sup> Sangseop Kim, *Determination of Wall Thickness and Height Limits when Cutting Various Materials with Wire Electric Discharge Machining Process* (School of Technology, Brigham Young University, Thesis, April 2005), 65.

Five different metals were tested which are commonly cut by wire-EDM machines. Namely: Aluminum 6061 T6, Yellow Brass SS360, 420 Stainless Steel, D2 Tool Steel at 25 to 30 RC, and D2 Tool Steel at 60 to 65 RC.<sup>59</sup>

Kim cut thin-walled sections ranging in thickness from 0.05 millimeters (0.002 inches) increasing incrementally by 0.05 millimeters (0.002 inches) until they reached a thickness of 0.30 millimeters (0.012 inches) from a block of material approximately 56 millimeters (2.2 inches) long and 25.4 millimeters (1 inch) square. Only one end of each section remained attached to the parent material.<sup>60</sup> A diagram depicting the layout of the test specimens can be seen in Figure 2.11.

**Figure 2.11** - Design and Layout of Thin-walled Sections for the Test Specimen<sup>61</sup>

<sup>59</sup> Ibid., 26

<sup>60</sup> Ibid., 24-25

<sup>61</sup> Ibid., 25

Through his research, Kim determined that there are significant differences in the height of the [thin-walled sections] as the thickness becomes smaller.<sup>62</sup> He also determined that there are significant differences in the height of the [thin-walled sections] when cutting different metals.<sup>63</sup> It will be possible to compare these conclusions to those presented at the end of this thesis in order to determine if there are differences due to the degree in which each of the thin-walled sections is constrained.

<sup>63</sup> Ibid., 66

## **3 Method and Procedures**

### **3.1 Introduction**

The sections in this chapter give an in-depth description of the methods and experimental procedures which were used in order to conduct the research for this thesis. These sections consist of: test materials, test blank design, machine parameters, measurement methods, and experimental design.

### **3.2 Test Materials**

As indicated earlier in this paper, five different types of metals were tested in order to observe the machining performance of wire-EDM in cutting thin sections from these different materials. These materials are Aluminum 6061 T6, Yellow Brass SS360, 420 Stainless Steel, D2 non-heat-treated tool steel 25-30 RC, and D2 heat-treated tool steel 60-65 RC. These materials were chosen because of their extensive use in the industrial sector, and their prominence for being machined by wire-EDM. It is assumed that, due to the properties and characteristics exhibited by these five metals, the testing and analyzation of these materials created a breadth of data and knowledge about these materials that can be used as a baseline from which industry can work and inferences can be drawn.

The physical properties, due to chemical composition, of these metals have a significant impact on the settings of the wire-EDM machine, and the speed with which

they can be machined. The two greatest factors due to chemical composition are the electrical conductivity and the vaporization points of the materials. Related to the vaporization point, but not as prolific, is the temperature at which melting in lieu of vaporization occurs. Table 3.1 lists the chemical compositions of the five different test materials.

**Table 3.1** - Chemical Composition of Test Materials

<b>Material</b>	<b>Composition by Weight %</b>
Aluminum 6061 T6	Al 98, Cr 0.04-0.35, Cu 0.15-0.4, Mg 0.8-1.2, Si 0.4-0.8
Yellow Brass SS360	Cu 60-63, Pb 2.5-3.7, Zn 35.5
420 Stainless Steel	C 0.15, Cr 13, Fe 85
D2 Tool Steel 25-30 RC	C 1.5, Cr 12, Fe 85.6, Mn 0.3, Mo 0.75, Si 0.3, V 0.9
D2 Tool Steel 60-65 RC	C 1.5, Cr 12, Fe 85.6, Mn 0.3, Mo 0.75, Si 0.3, V 0.9

This information was obtained from industry standards, and the data sheets provided by the manufacturers of the different metals are included in the appendix (see Appendix A). It should be understood that the weight percentages that are given in the preceding table represent averages, and the exact composition of the test materials will vary slightly from the percentages listed above. There are also other elements which may be found in small amounts in the test materials.

Electrical conductivity of the material being machined becomes a factor because it dictates the amount of current that can pass through it at a given time. The greater the electrical conductivity equates to more electrical current thus increasing the speed with which the material can be machined. Table 3.2 lists the electrical resistivity of the test materials.

**Table 3.2** - Electrical Resistivity of the Test Materials

<b>Materials</b>	<b>Electrical Resistivity</b>
Aluminum 6061 T6	$4e^{-006}$ ohm-cm
Yellow Brass SS360	$0.090 \times 10^{-6}$ $\Omega$ m
420 Stainless Steel	$5.5e^{-005}$ ohm-cm at 20°C
D2 Tool Steel 25-30 RC	0.196 $\mu\Omega$ m at 20°C
D2 Tool Steel 60-65 RC	0.196 $\mu\Omega$ m at 20°C

Other properties of interest that the test materials possess are their thermal conductivity, coefficient of thermal expansion (CTE), and hardness. The thermal conductivity of a material being machined by EDM will help to dictate the amount of material that each spark will remove and the resultant thickness of the heat affected zone. The lower the thermal conductivity of the material will result in a greater amount of material removal along with a thinner heat affected zone. This is due to the fact that a greater amount of the heat from each spark is maintained at the surface of the cut and kept from defusing into the material. Table 3.3 lists the thermal conductivity of the test materials.

**Table 3.3** - Thermal Conductivity of the Test Materials

<b>Materials</b>	<b>Thermal Conductivity</b>	
Aluminum 6061 T6	166.9 W/m - K	1160 BTU-in/hr-ft <sup>2</sup> - °F
Yellow Brass SS360	115 W/m - K	798 BTU-in/hr-ft <sup>2</sup> - °F
420 Stainless Steel	24.9 W/m - K	173 BTU-in/hr-ft <sup>2</sup> - °F
D2 Tool Steel 25-30 RC	20.9 W/m - K @ 95°C	145 BTU-in/hr-ft <sup>2</sup> - °F
D2 Tool Steel 60-65 RC	20.9 W/m - K @ 95°C	145 BTU-in/hr-ft <sup>2</sup> - °F

The CTE is important to consider because it will dictate the degree to which the overall part temperature needs to be controlled in order to achieve the desired part

accuracy. The CTE is the change in the material's size due to a change in the temperature of the part. Table 3.4 lists the CTE of the test materials.

**Table 3.4** - Coefficient of Thermal Expansion (CTE) of the Test Materials

<b>Materials</b>	<b>Coefficient of Thermal Expansion (CTE)</b>	
Aluminum 6061 T6	23.6 $\mu\text{m}/\text{m}\cdot^{\circ}\text{C}$ at 20°C	13.1 $\mu\text{in}/\text{in}\cdot^{\circ}\text{F}$ at 68°F
Yellow Brass SS360	20.5 $\mu\text{m}/\text{m}\cdot^{\circ}\text{C}$ at 20°C	11.4 $\mu\text{in}/\text{in}\cdot^{\circ}\text{F}$ at 68°F
420 Stainless Steel	10.3 $\mu\text{m}/\text{m}\cdot^{\circ}\text{C}$ at 20°C	5.72 $\mu\text{in}/\text{in}\cdot^{\circ}\text{F}$ at 68°F
D2 Tool Steel 25-30 RC	10.3 $\mu\text{m}/\text{m}\cdot^{\circ}\text{C}$ at 20°C	5.72 $\mu\text{in}/\text{in}\cdot^{\circ}\text{F}$ at 68°F
D2 Tool Steel 60-65 RC	10.3 $\mu\text{m}/\text{m}\cdot^{\circ}\text{C}$ at 20°C	5.72 $\mu\text{in}/\text{in}\cdot^{\circ}\text{F}$ at 68°F

In contrast to the data listed above, the hardness of the five test materials was obtained through testing each of the different materials. The material hardness was measured using a Rockwell hardness tester. In order to measure the hardness of the D2 heat-treated tool steel a 1.524 mm (0.06 inch) Brale diamond cone indicator was used with a force of 980.7 N (1000 Kgf). For the remainder of the materials a 1.587 mm (0.0625 inch) tungsten carbide ball was used with a force of 147.1 N (150 KGF). Each of the materials was tested five times. The three median test values were averaged in order to determine the hardness of each material. This data is documented in the appendix (see Appendix B). Table 3.5 shows the average of the three median test values and their conversion into Brinell Hardness for each of the test materials.

**Table 3.5** - Conversion of HRC and HRB to Brinell Hardness for the Test Materials

<b>Materials</b>	<b>Average</b>	<b>Brinell Hardness</b>
Aluminum 6061 T6	57.5 HRB	98
Yellow Brass SS360	74.2 HRB	126
420 Stainless Steel	86.5 HRB	167
D2 Tool Steel 25-30 RC	95.7 HRB	212
D2 Tool Steel 60-65 RC	62.8 HRC	701

### 3.3 Test Blank Design

The test blanks for this study are hexahedron cuboids that measure 76.2 millimeters (3 inches) long by 25.4 millimeters (1 inch) square. This allowed sufficient material for each of the thin-walled sections to be cut, and sufficient space between them so that they could be measured. Figure 3.1 is an isometric drawing showing the size and shape of the test blanks.

**Figure 3.1** - Size and Shape of Test Blanks (units: mm)

In order to enable the wire to be threaded through the test blank, 3.175 mm (.125 inch) holes were drilled through the center of each of the sections which were cut out of

the blanks. Figure 3.2 is a drawing that shows the location and diameter of each of the thread holes.

**Figure 3.2** - Layout of Thread Holes for the Test Blanks (units: mm)

A CNC program was created in Gibbs CAM, and the holes were drilled with one of the Hurco milling machines located in the Crabtree building. Due to the different materials, several CNC programs were generated to accommodate the different feed rates and are documented in the appendix (see Appendix C). Also, the holes were drilled in the D2 Tool Steel blanks before those requiring heat treating were hardened.

Six different thicknesses of thin-walled sections increasing incrementally in thickness by 0.05 millimeters (0.002 inches) from 0.05 millimeters (0.002 inches) to 0.30 millimeters (0.012 inches) were cut. This was achieved by cutting a line of hexahedron cuboids out of the center of the test blank leaving a thin-walled section between each of the cutouts. Both ends of the thin-walled sections remained attached to the parent

material thus constraining them as required. Figure 3.3 is a drawing indicating the layout of the thin-walled sections and the target thickness for each.

**Figure 3.3** - Drawing Indicating Layout of Thin-walled Sections and their Target Thickness

The target measurements for each of the thin-walled sections are represented in Figure 3.3. These target dimensions were used in the analysis of the specimens which is discussed in Chapter 4 of this thesis.

### 3.4 Machine Parameters

The machine parameters encompass those factors that dictate the operation of the machine and conditions within which it operates. The topics of discussion within this section are machine settings, cutting conditions, machining programs, and wire offset.

### 3.4.1 Machine Settings

The power settings utilized by the Sodick AQ325L were different for each of the different types of materials that were cut. These settings were defined at the beginning of each of the CNC programs and can be seen in the appendix (see Appendix D).

### 3.4.2 Cutting Conditions

The cutting conditions are the factors relative to the part being machined and the environment within which the machine exists and operates. Those factors listed in Table 3.6 are the cutting conditions selected from the machine's operating parameters during the setup prior to cutting each part.

**Table 3.6 - Cutting Conditions for Sodick AQ325L wire-EDM Machine**

Machine Dielectric Fluid	Deionized Water
Wire Diameter	0.24892 mm (0.0098 inches)
Wire Type	Brass (Intech Super Brass 900)
Work Setting	Al, Cu (for Brass), Steel (for D2 Tool Steel and Stainless Steel)
Work Thickness	29.972 mm (1.18 inches)
Machine	Punch
Nozzle Position	Open-U
Number of Passes	1,2, or 4

### 3.4.3 Machining Programs

Part of the object of this thesis is to observe the effects which a variation of roughing and finishing passes have with regard to a wire-EDM machine cutting thin-walled sections. Three different combinations of these passes were utilized; namely:

- Rough Cut with no Finishing Passes

- Rough Cut with one Finishing Pass
- Rough Cut with three Finishing Passes

As stated earlier, the difference in each subsequent pass is a reduction in the voltage and spark on-time resulting in a better surface finish and a thinner heat affected zone.

The cutting parameter of a roughing cut with two finishing passes was not run for two reasons. First, in some research performed by Mundt, there was very little difference observed between the results when comparing a roughing cut with two finishing passes to a roughing cut with three finishing passes. Second, in order to maintain the similarity to the research performed by Kim, a roughing cut with two finishing passes was omitted.

In order to run these three different cutting sequences it was necessary to write a CNC program for each of the sequences. Each of the programs is a compilation of the X Y cutting path and the machine settings. The three different CNC programs can be seen in the appendix (see Appendix E).

#### **3.4.4 Wire Offset**

Wire offset is defined as the distance from the center of the wire to the finished edge of the workpiece plus the arc gap. The arc gap is the distance between the electrode (in our case the wire) and workpiece during arcing when the dielectric fluid is in an ionized condition. In order to leave material to be removed by subsequent passes the wire offset needs to be increased with regards to the desired number of finishing passes and the type of material being machined. Table 3.7 lists the wire offsets which were used. The measurements which are reported in this table were converted from English units to metric due to the fact that the Sodick AQ 325L operates in English units.

**Table 3.7** - Offset Distances Used for Each Material and Required Passes (units: mm)

<b>Materials</b>	<b>Roughing Cut</b>	<b>Roughing Cut and one Finishing Pass</b>	<b>Roughing Cut and three Finishing Passes</b>
Aluminum 6061 T6	Roughing 0.1930	Roughing 0.2360 Finishing 0.1461	Roughing 0.2570 1 <sup>st</sup> Finishing 0.1669 2 <sup>nd</sup> Finishing 0.1369 3 <sup>rd</sup> Finishing 0.1321
Yellow Brass SS360	Roughing 0.1971	Roughing 0.2339 Finishing 0.1491	Roughing 0.2551 1 <sup>st</sup> Finishing 0.1600 2 <sup>nd</sup> Finishing 0.1349 3 <sup>rd</sup> Finishing 0.1331
420 Stainless Steel	Roughing 0.1661	Roughing 0.2009 Finishing 0.1359	Roughing 0.2179 1 <sup>st</sup> Finishing 0.1529 2 <sup>nd</sup> Finishing 0.1331 3 <sup>rd</sup> Finishing 0.1311
D2 Tool Steel 25-30 RC	Roughing 0.1661	Roughing 0.2009 Finishing 0.1359	Roughing 0.2179 1 <sup>st</sup> Finishing 0.1529 2 <sup>nd</sup> Finishing 0.1331 3 <sup>rd</sup> Finishing 0.1311
D2 Tool Steel 60-65 RC	Roughing 0.1661	Roughing 0.2009 Finishing 0.1359	Roughing 0.2179 1 <sup>st</sup> Finishing 0.1529 2 <sup>nd</sup> Finishing 0.1331 3 <sup>rd</sup> Finishing 0.1311

The same wire offsets were used for the 420 Stainless Steel, D2 Tool Steel 25-30 RC, and D2 Tool Steel 60-65 RC because the machine setting for steel was utilized.

### 3.4.5 Modification to Machine Default Settings

In beginning to cut the test specimens, utilizing the default settings of the wire-EDM machine, the EDM wire kept breaking. The rupture of the wire would occur during the first seconds of operation. This occurred on each of the three material settings used to machine the five metal types. In order to overcome this problem an adjustment of some of the default settings was required. Upon inspection of the CNC program documented

in appendix C of *Determination of Wall Thickness and Height Limits when Cutting Various Materials with Wire Electric Discharge Machining Process* by Sangseop Kim, Kim indicated that setting adjustments were necessary to perform his research. Spark on-time was lowered and the MAO changed for the lead in and rouging pass.

[MAO] is the parameter for establishing the criteria for machining stability. ['M'] defines the voltage level for judging stability in machining. ['A'] specifies how many number of times the OFF time should automatically be extended when the state of machining is judged unstable from the level defined by 'M'. ['O'] specifies a duration for the ON time which should be used when the state of machining is judged unstable from the level defined by 'M' [when running in TM pulse machining].<sup>64</sup>

The wire tension and wire speed were also reduced; however in contrast to the previous changes, the reduction of these parameters was made on all of the passes made by the wire. Tables displaying all of the machine settings used in this study for the three material settings used – aluminum, copper, and steel – can be seen in the appendix (see Appendix D).

### **3.5 Measurement Methods**

Two types of data were gathered from each of the test specimens. First, numerical data was obtained by measuring the thicknesses of each of the thin-walled sections. A Brown and Sharp Coordinate Measuring Machine (CMM) was used to measure each of the sections. The sensor head consisted of two pieces the Renishaw PH10MQ and the Renishaw SP600M. A 10 millimeter long tip was used which had a one millimeter diameter ball on the end. The software used to run the CMM was PC-DMIS version 3.7.3. The CNC program that was written to measure each of the test

---

<sup>64</sup> Sodick Co., Ltd, *Sodick Wire Cut-EDM AQ Series with LNIW Power Supply Ver. 1.0 (Instruction Manual)*, 2-2-5.

specimens can be seen in the appendix (see Appendix F). Measurements were taken in six different locations on each of the thin-walled sections; three on the top and three on the bottom. A measurement was taken close to each end of the section where it is attached to the parent material, and the other was taken close to the center of the section approximately three millimeters in from each end. The measurements taken at each end of the sections were acquired at a sufficient distance from the end in order to ensure that the inside corner radius left by the EDM wire did not affect the data. Figure 3.4 is a diagram showing a blown-up section of a test specimen with a red X indicating the approximate locations where measurements were taken on the top and bottom of one of the thin-walled sections.

**Figure 3.4** - Approximate Location where Measurements were Taken

The CNC program that was written for the CMM and used to measure each of the sections followed the same sequence for each of the test specimens. Each location where a measurement was taken in the sequence was documented. Figure 3.5 is a drawing depicting of the end view of a test specimen. The numbers indicated on the drawing represent the sequence in which the measurements were taken on a given web and are also used in the documentation of the data obtained.

**Figure 3.5** - Sequence in which Measurements were Taken

This drawing depicting the test specimen is oriented so that you are looking at the end closest to the web with a target thickness of .30 millimeters. Numbers 1 – 3 were taken on the top of the test specimen and numbers 4 – 6 were taken on the bottom.

The second type of data obtained was a visual inspection of each of the thin-walled sections. The visual inspection was used to look for any material that was obviously missing from the center or edges of each of the sections or any bending/deflection of the web. Defects that were looked for were holes eroded through the center of the sections, and/or material that was eroded away from the top or bottom of the sections. The data obtained through this inspection was recorded as pass or fail. If either of the defects existed then that thin-walled section was recorded as a failure.

### **3.6 Experimental Design**

Due to the nature of the machining and measuring processes there are several issues which constrained and dictated the experimental design. The factors being studied were not constrained to high/low settings, so they would not fit into a factorial design. Also, in order to keep run times and number of test specimens to a reasonable level and in order to simulate industrial operations to a greater degree, an entire set of the six sizes of thin-walled section were cut from each test blank. The measurements of the resultant thicknesses of the thin-walled sections were taken in a similar manner through the application of the same reasoning. The order in which each of the test specimens were machined and measured was randomized in order to increase the statistical confidence of the experiment. Each of the test specimens was assigned a number, and then a random number generator was used to select the run order. This was performed twice so that a different randomized run order could be used for the machining and measuring processes. All of this information can be seen in Table 3.8.

**Table 3.8 - Run Order for Machining and Measuring Processes**

Part #	Material	Passes	Random Number	EDM Run Order	Random Number	Measure Run Order
1	Aluminum 6061 T6	Rough, 0 Finish	0.379196	13	0.289062	9

## 4 Results and Analysis

### 4.1 Introduction

The sections in this chapter discuss the data that was obtained through the experiment and its subsequent analysis. In section 4.2 the data obtained through visual inspection and its subsequent analysis is presented. Definitions of the types of failures are delineated and then used in the analysis. The data is separated and discussed according to the different material types. In section 4.3 the numerical data which was obtained is presented and analyzed. Several statistical values – the mean, average difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  – were calculated in order to describe the data. ANOVA tests were also performed on the data in order to facilitate comparisons between the materials according to the cutting parameters utilized. In section 4.4 the  $C_p$  and  $C_{pk}$  values that were calculated for each data set were used to compare the distribution of the data values for each of the different materials. It is important to note that these values are used for comparison only and only have significance to the comparisons made in this thesis.  $C_p$  and  $C_{pk}$  formulas require specification limits in their calculations, so specification limits of  $\pm 0.03$  millimeters (.0012 inches) were arbitrarily chosen. To facilitate the desired comparison the only requirement was that the specification limits be the same in all the calculations. The designated limits were chosen because they enabled a positive  $C_{pk}$  value to be calculated for virtually all of the data sets.

## 4.2 Visual Inspection Test of Thin-Walled Sections

A visual inspection test was performed on each of the thin-walled sections in order to determine if portions of the sections had been eroded away or if permanent deflection of the section had occurred. It should be noted that deflection of the thin-walled sections was likely caused by stresses introduced into the material through the machining process. Kim performed test on similar stock in order to determine if there were any residual forces in the materials. He observed bending which occurred in the direction of the last side cut by the wire-EDM machine. He thus concluded that there were no residual stresses in the parent material.<sup>65</sup> The tests for this thesis were performed under the same assumption. Four terms were used in order to describe defects which occurred while machining the thin-walled sections: depleted, notch, bent/notch, and bent. Each of these terms is further defined below.

- Depleted – this describes a thin-walled section which was completely eroded away. Often there were small tabs left on the parent material where the section should be attached due to the corner radius left by the round wire. Pictures of test specimens depicting this type of defect are shown in Figure 4.1.
- Notch – this describes a thin-walled section which had a major portion of the thin-walled section missing, and occurred in several different forms. Sometimes the center of the section was missing so that there were only tabs extending out from the parent material on each side, while at other times a ‘U’ or ‘V’ shaped notch was cut out of the top and/or bottom of the section. The difference between this

<sup>65</sup> Sangseop Kim, *Determination of Wall Thickness and Height Limits when Cutting Various Materials with Wire Electric Discharge Machining Process* (School of Technology, Brigham Young University, Thesis. April 2005), 35-40.

**Figure 4.1** - Test Specimens Demonstrating a Defect where a Thin-walled Section is Depleted

type of defect and the “depleted” description is that with the “notch” there was a sufficient amount of material left in order to obtain a measurement of the thickness of the thin-walled section. Figure 4.2 shows pictures of test specimens illustrating this type of defect.

**Figure 4.2** - Test Specimens Demonstrating a Notch Defect in the Thin-walled Section

- Bent/Notch – this describes a thin-walled section where a notch was present and where the entire section or portions of the section had deflected. Often, the deflection was confined to a small portion of the thin-walled section or the

deflection was evenly spread across the web so that it resembled a parenthesis when looked at directly from the top or bottom. In these cases it was possible to obtain a measurement where there was not a notch present in the section. At times, in conjunction with a notch the edge created by the notch curled or bent to a degree such that it was not possible to take a measurement. Figure 4.3 shows pictures of these types of defects.

**Figure 4.3** - Test Specimens Demonstrating a Bent/Notch Defect

- Bent – this describes a thin-walled section which had deflected but was not missing any portions of the section. It was noted that the deflection always occurred away from the final cut, or in other words the deflection occurred in a direction that moved the section away from the wire as it was cutting the second side of the web. Figure 4.4 is a picture of this type of defect.

**Figure 4.4** - Test Specimens Demonstrating a Bent Failure for the Thin-walled Sections

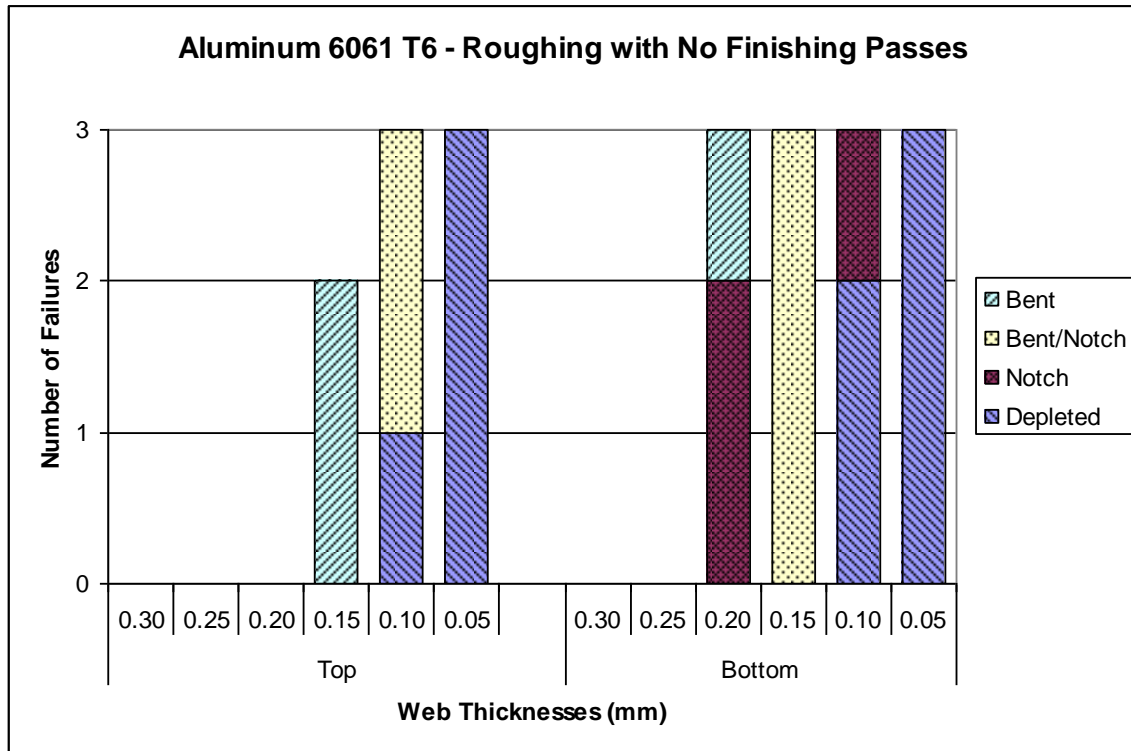

Each of the thin-walled sections was evaluated and records were generated when any of the four visual inspection failures just described was observed. This data was compiled and can be seen in its entirety in the appendix (see Appendix G).

An analysis of the visual inspection data, which follows, is separated into sections by material type and by the number of finishing passes that were used. Three replications for each of the cutting parameters were performed in this study, so each of the graphs in this section represents the compilation of the data for those replications.

#### **4.2.1 Aluminum 6061 T6 – Visual Inspection Data and Analysis**

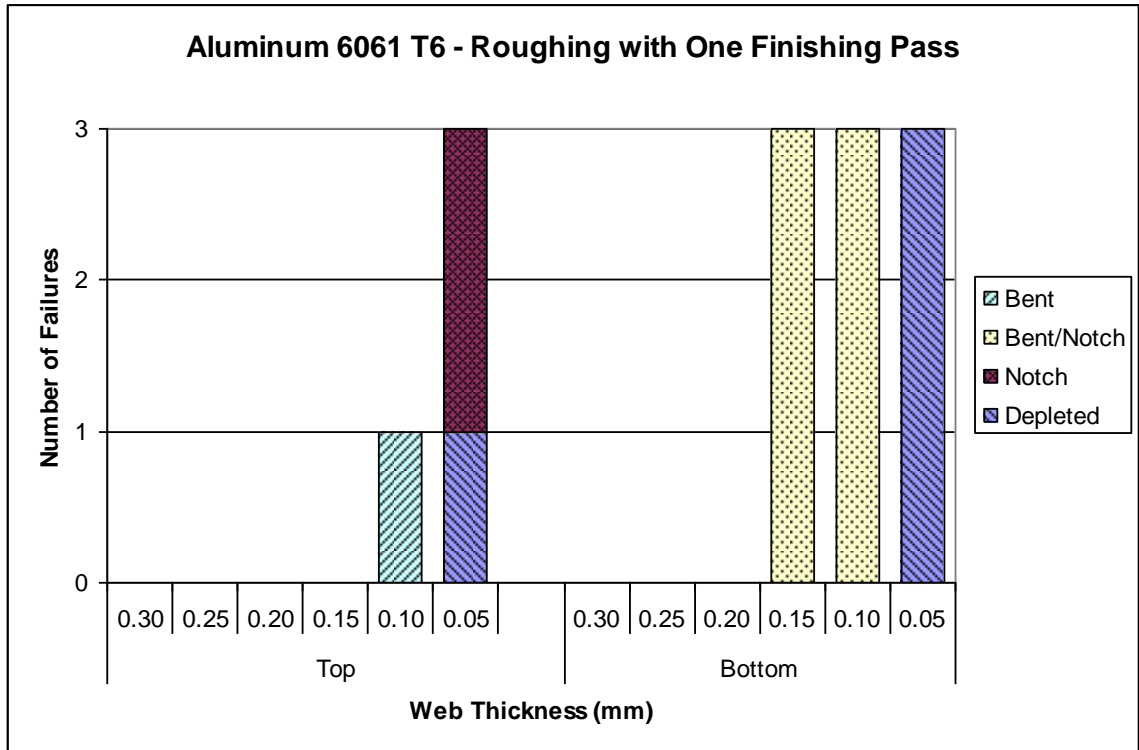

Figure 4.5 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from Aluminum 6061 T6 while utilizing the machining parameters of a roughing pass with no finishing passes. As indicated by the chart, the thin-walled sections with target thicknesses of 0.10 and 0.05 millimeters (.004 and .002 inches) were almost totally vaporized during the machining process. The sections with a target thickness of 0.15 millimeters (.006 inches) demonstrated a significant difference in quality between the top and the bottom of the sections. The top of these sections were

slightly bent, but the bottom of each also had significant notches in them. The sections with a target thickness of 0.20 millimeters (.008 inches) did not have any defects on the top of the sections, but the bottom of the sections each had slight defects, either a bend or a slight notch.

**Figure 4.5** - Visual Inspection Failures of Thin-walled Sections of Aluminum 6061 T6 – Roughing with No Finishing Passes

Figure 4.6 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from Aluminum 6061 T6 while utilizing the machining parameters of a roughing pass with one finishing pass. As indicated by the chart, the thin-walled sections with a target thickness of 0.05 millimeter (.002 inch) were almost entirely vaporized. Only one of the sections with a target thickness of 0.10 millimeter (.004 inch)

**Figure 4.6** - Visual Inspection Failures of Thin-walled Sections of Aluminum 6061 T6 – Roughing with One Finishing Pass

had a defect on the top of the section – a slight bend – , but the bottom of the sections had significant notches and had deflected significantly. The bottom of each of the sections with a target thickness of 0.15 millimeter (.006 inch) had a small notch in it and was slightly bent.

Figure 4.7 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from Aluminum 6061 T6 while utilizing the machining parameters of a roughing pass with three finishing passes. The sections with a target thickness of 0.05 millimeter (.002 inch) were each slightly bent on the top of the sections while each section had a large notch in the bottom where some of the section had been eroded. The

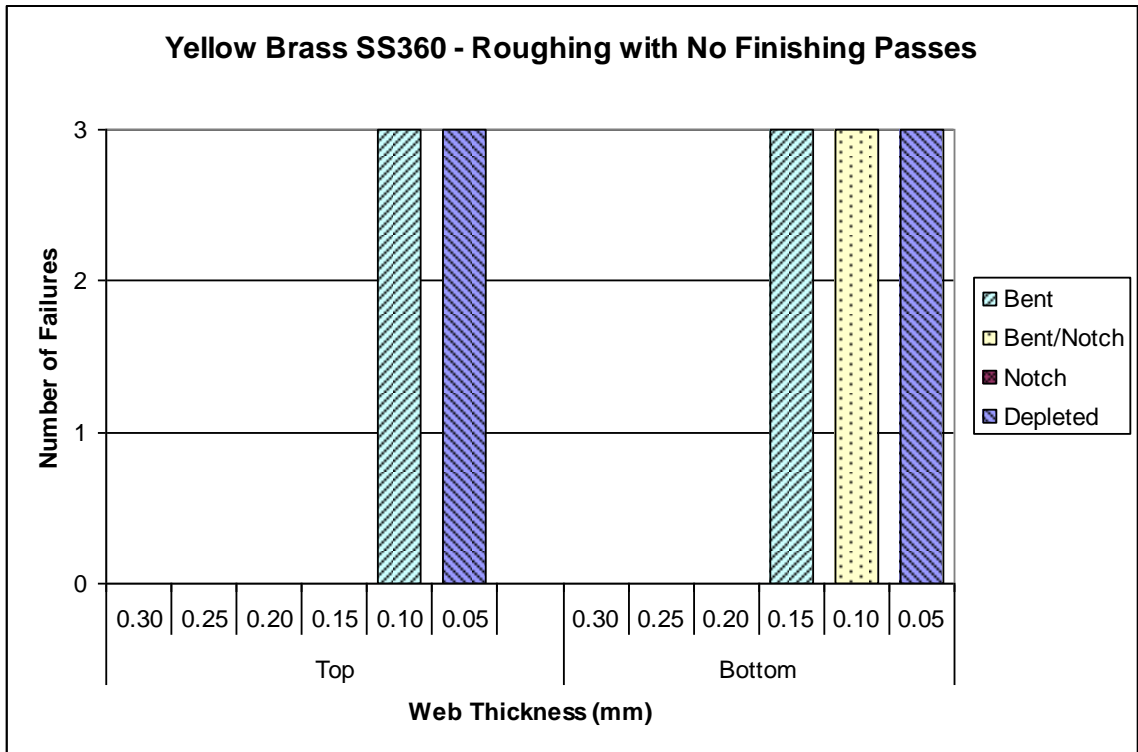

**Figure 4.7** - Visual Inspection Failures of Thin-walled Sections of Aluminum 6061 T6 – Roughing with Three Finishing Passes

bottom of each of the sections with a target thickness of 0.10 millimeter (.004 inch) was slightly bent and also exhibited small notches.

By comparing the data depicted in the three preceding charts, which represent failures determined through visual inspection while cutting thin-walled section from Aluminum 6061 T6, it can be seen that both the number and degree of failure decreased when the number of finishing passes was increased. Thus, a roughing pass and three finishing passes obtained the best results. Also, it is interesting to note that all of the test specimens exhibited a greater number and more drastic failures on the bottom of the thin-walled sections as compared to those found on the top of the corresponding sections. Although the data clearly exhibits this pattern, the cause of this phenomenon is unknown.

#### 4.2.2 Yellow Brass 360 – Visual Inspection Data and Analysis

Figure 4.8 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from Yellow Brass SS360 while utilizing the machining parameters of a roughing pass with no finishing passes. The sections with a target thickness of 0.05 millimeter (.002 inch) were totally eroded during the machining process. The top of the sections with a target thickness of 0.10 millimeter (.004 inch) were bent while the bottom of each of the corresponding sections also had a large notch where part of it had been eroded. While the top of the sections with a target thickness of 0.15 millimeter (.006 inch) exhibited no defects the bottom of these same sections were slightly bent.

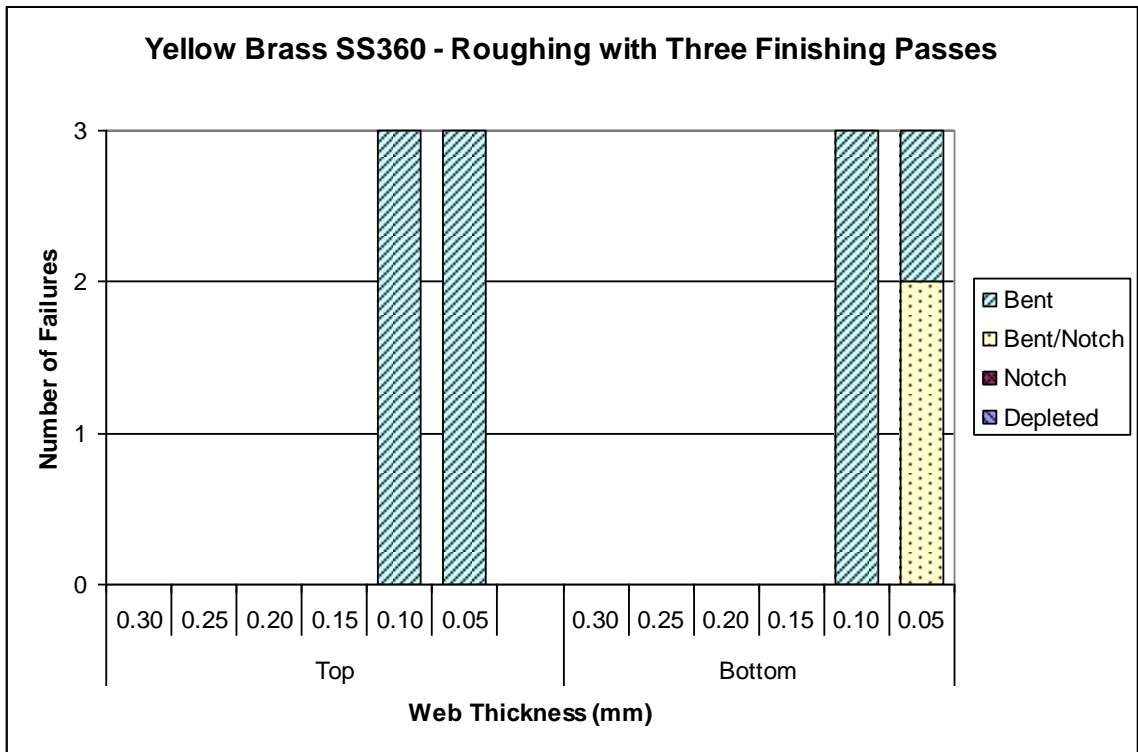

**Figure 4.8** - Visual Inspection Failures of Thin-walled Sections of Yellow Brass SS360 – Roughing with No Finishing Passes

Figure 4.9 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from Yellow Brass SS360 while utilizing the machining parameters of a roughing pass with one finishing pass. Each of the sections with a target thickness of 0.05 millimeter (.002 inch) was bent and contained a notch, but the degree of bending and size of the notches was significantly greater in the bottom of each section. The sections with a target thickness of 0.10 millimeter (.004 inch) were slightly bent on the top of the sections and exhibited a slightly greater degree of bending on the bottom of the corresponding sections.

**Figure 4.9** - Visual Inspection Failures of Thin-walled Sections of Yellow Brass SS360 – Roughing with One Finishing Pass

Figure 4.10 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from Yellow Brass SS360 while utilizing the machining parameters of a roughing pass with three finishing passes. The top of the sections with a target thickness of 0.05 millimeter (.002 inch) were bent while the bottom of two of the sections were both bent and notched. Unlike the other two, the bottom of the third section was only bent. The sections with a target thickness of 0.10 millimeter (.004 inch) exhibited a similar degree of slight bending on both the top and bottom of the sections.

**Figure 4.10** - Visual Inspection Failures of Thin-walled Sections of Yellow Brass SS360 – Roughing with Three Finishing Passes

By comparing the data depicted in the three preceding charts, which represent failures determined through visual inspection while cutting thin-walled sections from

Yellow Brass SS360, it can be seen that both the number and degree of failures decreased when the number of finishing passes was increased. Thus, a roughing pass and three finishing passes obtained the best results. Although not as pronounced as the failures in Aluminum 6061 T6, the bottoms of the thin-walled sections cut from Yellow Brass SS360 also displayed a greater number and more dramatic failures than did the tops of the same sections.

#### 4.2.3 420 Stainless Steel – Visual Inspection Data and Analysis

Figure 4.11 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from 420 Stainless Steel while utilizing the machining parameters of

**Figure 4.11** - Visual Inspection Failures of Thin-walled Sections of 420 Stainless Steel – Roughing with No Finishing Passes

a roughing pass with no finishing passes. As indicated by the chart, the sections with a target thickness of 0.05 millimeter (.002 inch) were completely eroded during the machining process. The top of the sections with a target thickness of 0.10 millimeter (.004 inch) were free of defects, but the bottom of the sections were each bent and had fairly large notches in them where some of the material had been consumed during the machining process. The bottom of one of the sections with a target thickness of 0.15 millimeter (.006 inch) was slightly bent while the other sections with the same target thickness were free of defects.

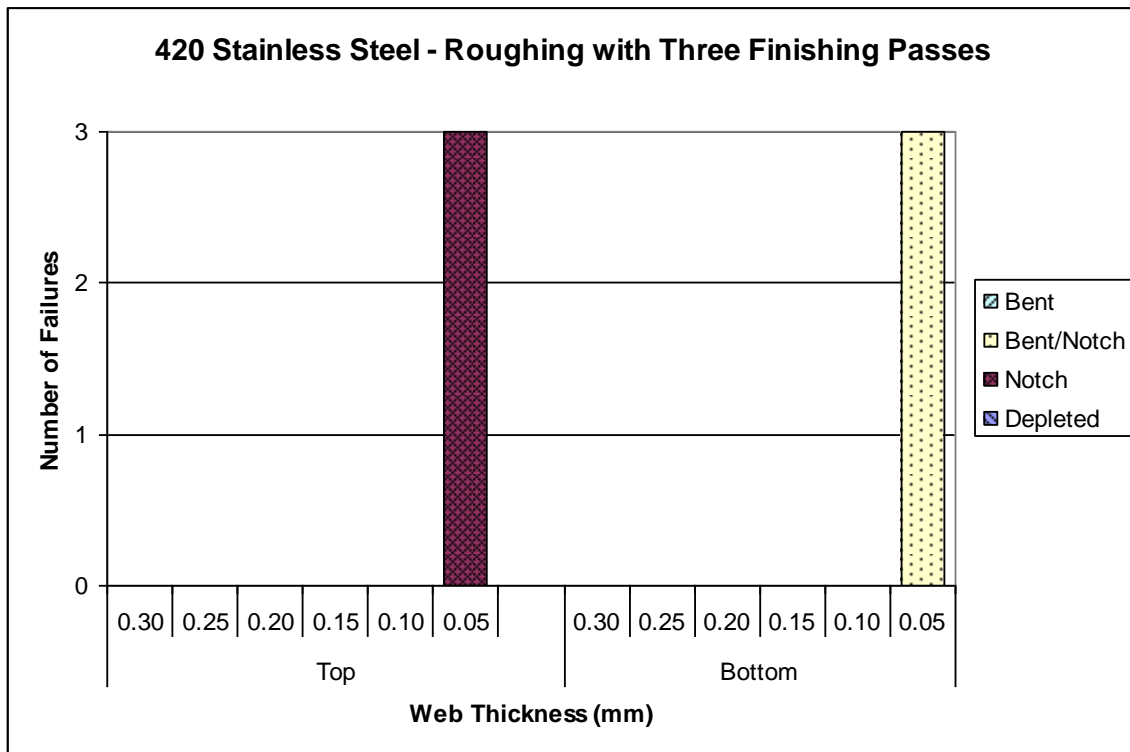

Figure 4.12 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from 420 Stainless Steel while utilizing the machining parameters of

**Figure 4.12** - Visual Inspection Failures of Thin-walled Sections of 420 Stainless Steel – Roughing with One Finishing Pass

a roughing pass with one finishing pass. Both the top and bottom of the sections with a target thickness of 0.05 millimeter (.002 inch) were slightly bent and contained fairly large notches which were comparable in size on the top and bottom. Two of the sections with at target thickness of 0.10 millimeter (.004 inch) displayed very slight bending on the bottom of the sections.

Figure 4.13 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from 420 Stainless Steel while utilizing the machining parameters of a roughing pass with three finishing passes. The sections with a target thickness of 0.05 millimeter (.002 inch) were the only sections that displayed any defects. The top of the

**Figure 4.13** - Visual Inspection Failures of Thin-walled Sections of 420 Stainless Steel – Roughing with Three Finishing Passes

sections each had large notches in them while the bottom of the sections had small notches and were very slightly bent.

By comparing the data depicted in the three preceding charts, which represent failures determined through visual inspection while cutting sections from 420 Stainless Steel, it can be seen that both the number and degree of failures decreases when the number of finishing passes was increased. While the first two cutting parameters discussed, roughing with no finishing passes and roughing with one finishing pass, exhibited the same characteristic of having more dramatic failures on the bottoms of the thin-walled sections as compared with those found on the tops of the sections, the third cutting parameter, roughing with three finishing passes, demonstrated the opposite tendency. That is, the tops of the sections had more dramatic failures than did the bottoms of the same sections.

#### **4.2.4 D2 Tool Steel 25-30 RC – Visual Inspection Data and Analysis**

Figure 4.14 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from D2 Tool Steel at 25 to 30 RC while utilizing the machining parameters of a roughing pass with no finishing passes. The sections with a target thickness of 0.05 millimeter (.002 inch) were completely eroded during the machining process. The tops of the sections with a target thickness of 0.10 millimeter (.004 inch) did not contain any defects, but the bottom of those sections each had a large notch in them where some of the material had been eroded during the machining process.

**Figure 4.14** - Visual Inspection Failures of Thin-walled Sections of D2 Tool Steel 25-30 RC – Roughing with No Finishing Passes

Figure 4.15 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from D2 Tool Steel at 25 to 30 RC while utilizing the machining parameters of a roughing pass with one finishing pass. The only defective sections observed with this material were the sections with a target thickness of 0.05 millimeter (.002 inch). Each of the sections had a notch in both the top and the bottom of the section. The bending of these sections refers to curling of the material around the edges of the notch. In all of the observed cases the direction of the curling was toward the side of the web that was cut last. This being the case, the curling had to have occurred on the final pass of the wire, but the cause of the curling could not be determined from this research.

**Figure 4.15** - Visual Inspection Failures of Thin-walled Sections of D2 Tool Steel 25-30 RC – Roughing with One Finishing Pass

Figure 4.16 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from D2 Tool Steel at 25 to 30 RC while utilizing the machining parameters of a roughing pass with three finishing passes. The sections with a target thickness of 0.05 millimeter (.002 inch) were the only sections containing defects while utilizing the specified machining parameters. The top of the sections each had a large notch in them while the bottom of the sections each had two smaller notches.

**Figure 4.16** - Visual Inspection Failures of Thin-walled Sections of D2 Tool Steel 25-30 RC – Roughing with Three Finishing Passes

By comparing the data depicted in the three preceding charts, which represent failures determined through visual inspection while cutting thin-walled sections from D2 Tool Steel at 25 to 30 RC, it can be seen that both the number and degree of failures decreased when the number of finishing passes was increased. The bottoms of the defective sections demonstrated a greater number and degree of failure while utilizing a roughing with no finishing passes. The failures observed between the tops and bottoms of the sections while utilizing a roughing with one finishing pass were relatively equal. While utilizing a roughing with three finishing passes the failures on the tops of the sections were more significant than those on the bottoms of the sections.

#### 4.2.5 D2 Tool Steel 60-65 RC – Visual Inspection Data and Analysis

Figure 4.17 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from D2 Tool Steel at 60 to 65 RC while utilizing the machining parameters of a roughing pass with no finishing passes. The sections with a target thickness of 0.05 millimeter (.002 inch) were totally eroded during the machining process. Two of the sections with a target thickness of 0.10 millimeter (.004 inch) exhibited relatively small notches on the bottom of the sections while the third and the top of all the sections did not exhibit any defects.

**Figure 4.17** - Visual Inspection Failures of Thin-walled Sections of D2 Tool Steel 60-65 RC – Roughing with No Finishing Passes

Figure 4.18 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from D2 Tool Steel at 60 to 65 RC while utilizing the machining parameters of a roughing pass with one finishing pass. As can be seen from the chart, the only sections that exhibited any defects were those that had a target thickness of 0.05 millimeters (.002 inches). Each of these sections had a large notch in both the top and bottom of the section. In some cases, the entire center of the section was missing from the top to the bottom leaving large tabs on each side attached to the parent material.

**Figure 4.18** - Visual Inspection Failures of Thin-walled Sections of D2 Tool Steel 60-65 RC – Roughing with One Finishing Pass

Figure 4.19 is a chart depicting the visual inspection data obtained after cutting thin-walled sections from D2 Tool Steel at 60 to 65 RC while utilizing the machining

**Figure 4.19** - Visual Inspection Failures of Thin-walled Sections of D2 Tool Steel 60-65 RC – Roughing with Three Finishing Passes

parameters of a roughing pass with three finishing passes. The only sections containing defects while utilizing the aforementioned cutting parameters were those that had a target thickness of 0.05 millimeters (.002 inches). One of the sections had a large notch in both the top and the bottom and a hole in the center. The other two sections were missing the entire center from the top to the bottom of the specimens.

By comparing the data depicted in the tree proceeding charts, which represent failures determined through visual inspection while cutting thin-walled sections from D2 Tool Steel at 60 to 65 RC, it can be observed that better results are achieved through the use of finishing passes. As to failures observed through visual inspection of the thin-walled sections, there is no difference in the number of failures observed while using one

or three finishing passes. However, while utilizing a roughing with no finishing passes both the degree and number of failures increased. Also, while utilizing a roughing with no finishing passes the number and degree of failures was greater on the bottoms of the sections as compared to those observed on the tops of the same sections. While utilizing a roughing with one finishing pass and a roughing with three finishing passes there is no observable difference between the failures on the tops and the bottoms of the thin-walled sections.

### **4.3 Measurement of Thin-Walled Sections and Statistical Analysis**

The following sections contain the analysis of the numerical data which was obtained from the test specimens. The analysis of the data is separated according to the material types that were tested. Charts indicating each of the data sets used and their distributions are given. Black dots were used on these graphs to indicate each data point, and a red diamond was used to indicate the target thickness for each thin-walled section. Tables follow each of these charts which list the mean, the mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each individual data set. In order to increase the reliability of the statistical analysis, any measurements that were taken on a thin-walled section which failed the visual inspection test was eliminated from the data set.

An ANOVA test was performed on the numerical data that was obtained by measuring the thickness of each of the thin-walled sections with a CMM. The complete statistical report of this analysis can be seen in the appendix (see Appendix H). Three different aspects of each data set were tested as to its significance: the number of finishing passes used, the thicknesses of the thin-walled sections, and the location from

which the measurements were taken – in reference to the top and bottom of the test specimen. A second ANOVA test was performed in order to compare the data sets obtained for the three different cutting parameters according to the material that was cut. The complete statistical report for this test can be seen in the appendix (see Appendix I). Tables, according to material type, listing the P-values obtained from this statistical analysis are displayed in the following sections. A third ANOVA test was performed in order to compare the data sets obtained for the five different materials according to the cutting parameters that were used to cut the materials. The complete statistical report for this ANOVA test can be seen in the appendix (see Appendix J). A table containing the P-values for each of these comparisons is given followed by a graph giving a visual interpretation of this data.

#### **4.3.1 Aluminum 6061 T6 – Statistical Analysis**

Figure 4.20 indicates the data set that was used in the statistical analysis for Aluminum 6061 T6 while utilizing cutting parameters of a roughing with no finishing passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) and 0.10 millimeters (.004 inches) failed the visual inspection test, so there are no data points represented at these thicknesses. Also, several of the 0.15 millimeter (.006 inch) sections failed the visual inspection test thus reducing the number of data points indicated at that thickness.

**Figure 4.20** - Data Set Used for Aluminum 6061 T6 - Roughing with No Finishing Passes

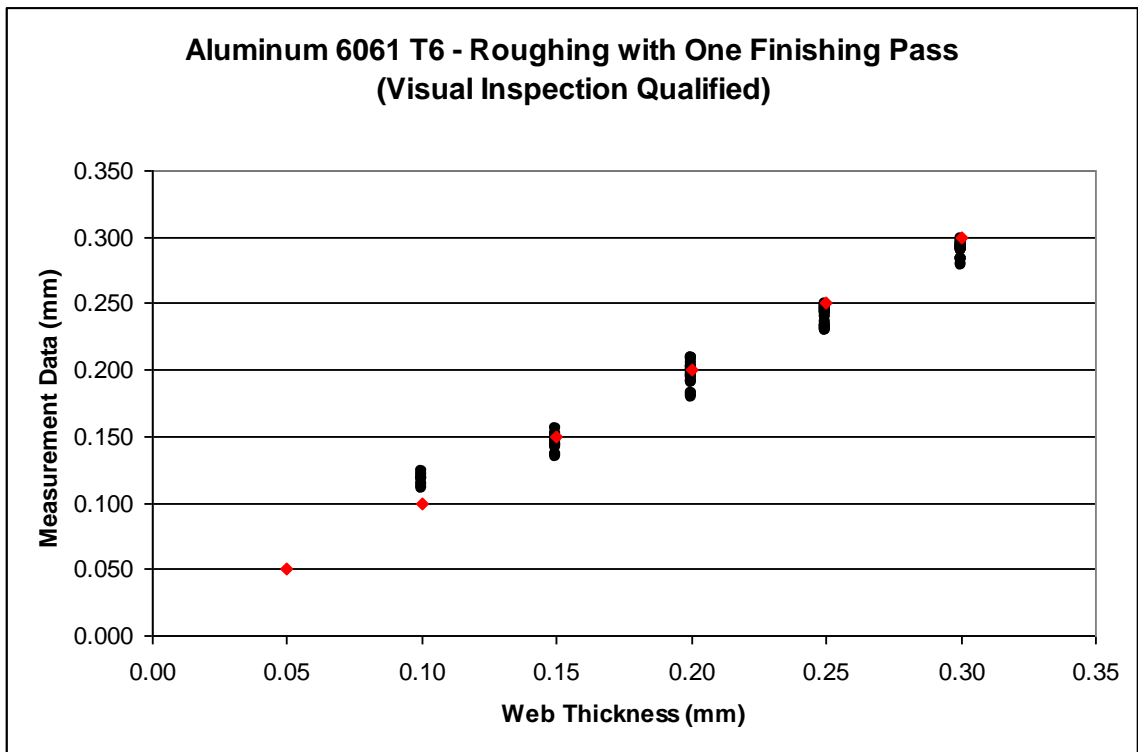

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.1. The mean for each data set is smaller than the respective target value. The ANOVA test indicated that this data is

**Table 4.1** - Aluminum 6061 T6 - Statistics for Roughing with No Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.273	-0.027	0.008238	1.2139	0.1326
0.250	0.226	-0.024	0.006582	1.5193	0.2814
0.200	0.170	-0.030	0.006708	1.4907	-0.0166
0.150	0.128	-0.022	0.001528	6.5465	1.8185
0.100	-	-	-	-	-
0.050	-	-	-	-	-

statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

Figure 4.21 indicates the data set that was used in the statistical analysis for Aluminum 6061 T6 while utilizing cutting parameters of a roughing with one finishing pass. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at that thickness. Also, several of the 0.10 millimeter (.004 inch) and 0.15 millimeter (.006 inch) sections failed the visual inspection test thus reducing the number of data points indicated at those thicknesses.

**Figure 4.21** - Data Set Used for Aluminum 6061 T6 - Roughing with One Finishing Pass

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.2. The mean for each data set representing target thicknesses from 0.30 to 0.15 millimeters (.012 to .006 inches) is smaller than the respective target value while the mean for the data set with a target value of 0.10 millimeters (.004 inches) is greater than the target value. The ANOVA test indicated that this data is statistically significant from the target values and has a combined t-value of 0.0025 for the specified parameters.

**Table 4.2** - Aluminum 6061 T6 - Statistics for Roughing with One Finishing Pass Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.290	-0.010	0.005237	1.9094	1.2977
0.250	0.241	-0.009	0.006964	1.4360	0.9839
0.200	0.196	-0.004	0.009149	1.0930	0.9453
0.150	0.144	-0.006	0.006572	1.5215	1.2285
0.100	0.117	0.017	0.004561	2.1926	0.9501
0.050	-	-	-	-	-

Figure 4.22 indicates the data set that was used in the statistical analysis for Aluminum 6061 T6 while utilizing cutting parameters of a roughing with three finishing passes. All of the sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at that thickness. Several of the 0.10 millimeter (.004 inch) sections failed the visual inspection test thus reducing the number of data points indicated at this thickness.

**Figure 4.22** - Data Set Used for Aluminum 6061 T6 - Roughing with Three Finishing Passes

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.3. The mean for each data set is larger than each of the respective target values. The ANOVA test indicated that this data

**Table 4.3** - Aluminum 6061 T6 - Statistics for Roughing with Three Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.305	0.005	0.004840	2.0660	1.6949
0.250	0.253	0.003	0.006082	1.6441	1.4766
0.200	0.207	0.007	0.007617	1.3129	1.0236
0.150	0.161	0.011	0.007302	1.3694	0.8597
0.100	0.103	0.003	0.007672	1.3034	1.1683
0.050	-	-	-	-	-

is statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

The ANOVA test further indicated that there was a significant difference in the data when the measurements that were taken from the tops of the thin-walled sections were compared to those taken from the bottoms of the sections. A t-value of 0.0031 was observed.

Figure 4.23 is a graph depicting the accuracy of cutting thin-walled sections from Aluminum 6061 T6 while utilizing the three cutting parameters previously specified. Each of the calculated mean values for the respective target thicknesses and cutting parameters were subtracted from the target value in order to generate the values represented on this graph. This effectually makes 0.00 the target. Upper and lower

Figure 4.23 - Aluminum 6061 T6 - Accuracy in Cutting Thin-walled Sections (mean minus target)

specification limits were also indicated at  $\pm 0.005$  millimeters. The accuracy obtainable by each of the cutting parameters can be readily seen along with a comparison of the cutting parameters.

A second ANOVA test was performed in order to determine the statistical significance between cutting parameters when machining the same material type. Table 4.4 lists the P-values that were generated from the ANOVA test. Any P-value which is greater than 0.05 indicates that there is not a statistically significant difference between the data sets being compared. Therefore, there is no statistical difference between the data obtained when comparing any of the cutting parameters utilized for any of the section target thicknesses when cutting Aluminum 6061 T6.

**Table 4.4** - Aluminum 6061 T6 - P-values of Comparisons between Cutting Parameters

Target Thickness	No Finishing to One Finishing	No Finishing to Three Finishing	One Finishing to Three Finishing

Figure 4.24 is a graph of the calculated P-values for the comparisons between cutting parameters while machining Aluminum 6061 T6. None of the P-values are located below the line indicating statistical significance which is at 0.05. Therefore, statistically, there exists no significant difference between the data sets generated by the three different cutting parameters used in this study.

Figure 4.24 - Aluminum 6061 T6 – Statistical Significance Comparison of Cutting Parameters by P-values

A third ANOVA test was performed on each data set of a thin-walled section according to the number of finishing passes that were utilized in order to compare the effect of material type. This test generated a P-value which indicates if there is a statistically significant difference between the data sets of the five different materials. Table 4.5 lists all of the P-values obtained through the ANOVA test in comparing the data sets for Aluminum 6061 T6 to the data sets for the other four materials.

**Table 4.5** - P-values Indicating Statistical Significance between Aluminum 6061 T6 and ...

	0.05	-	-	-	-

A graph depicting the relationships between each of the P-values can be seen in Figure 4.25. Included in this graph is a pink line with a P-value of 0.05. Any of the values above this line indicate that there is no statistical difference between the data sets while all of the values located below the line demonstrate that there is a statistical difference between the data sets.

When utilizing the machining parameters of a roughing with no finishing passes it can be seen that there is no statistical difference between the data sets for Aluminum 6061 T6 and D2 Tool Steel at 25 to 30 RC. There is also no significant statistical difference between the data sets with a section target thickness of 0.15 millimeters (.006 inches) for the Yellow Brass SS360 and the 420 Stainless Steel. All other data sets exhibited a statistically significant difference.

**Figure 4.25** - Statistical Significance of Aluminum 6061 T6 to the Other Four Materials

When utilizing the machining parameters of a roughing with one finishing pass there was no statistically significant difference for the majority of the comparative data sets. For the section thicknesses with a target value of 0.30 and 0.25 millimeters (.012 and .010 inches) the only material that exhibited a statistically significant difference is the Yellow Brass SS360. Both the Yellow Brass SS360 and the D2 Tool Steel at 60 to 65 RC had statistically significant data sets at the target section thickness of 0.20 millimeters (.008 inches). None of the data sets with a target thickness of 0.15 millimeters (.006 inches) demonstrated statistical significance, but all of the materials with data exhibited statistical significance when the target section thickness was 0.10 millimeters (.004 inches).

When utilizing the machining parameters of a roughing with three finishing passes the majority of the comparative data sets demonstrated statistical significance. The only exceptions to this being the D2 Tool Steel at 25 to 30 RC with section target thicknesses of 0.25, 0.20, and 0.10 millimeters (.010, .008, and .004 inches). The 420 Stainless Steel and the D2 Tool Steel at 60 to 65 RC data sets were also not significant with a section target thickness of 0.10 millimeters (.004 inches).

#### 4.3.2 Yellow Brass SS360 – Statistical Analysis

Figure 4.26 indicates the data set that was used in the statistical analysis for Yellow Brass SS360 while utilizing cutting parameters of a roughing with no finishing

**Figure 4.26** - Data Set Used for Yellow Brass SS360 - Roughing with No Finishing Passes

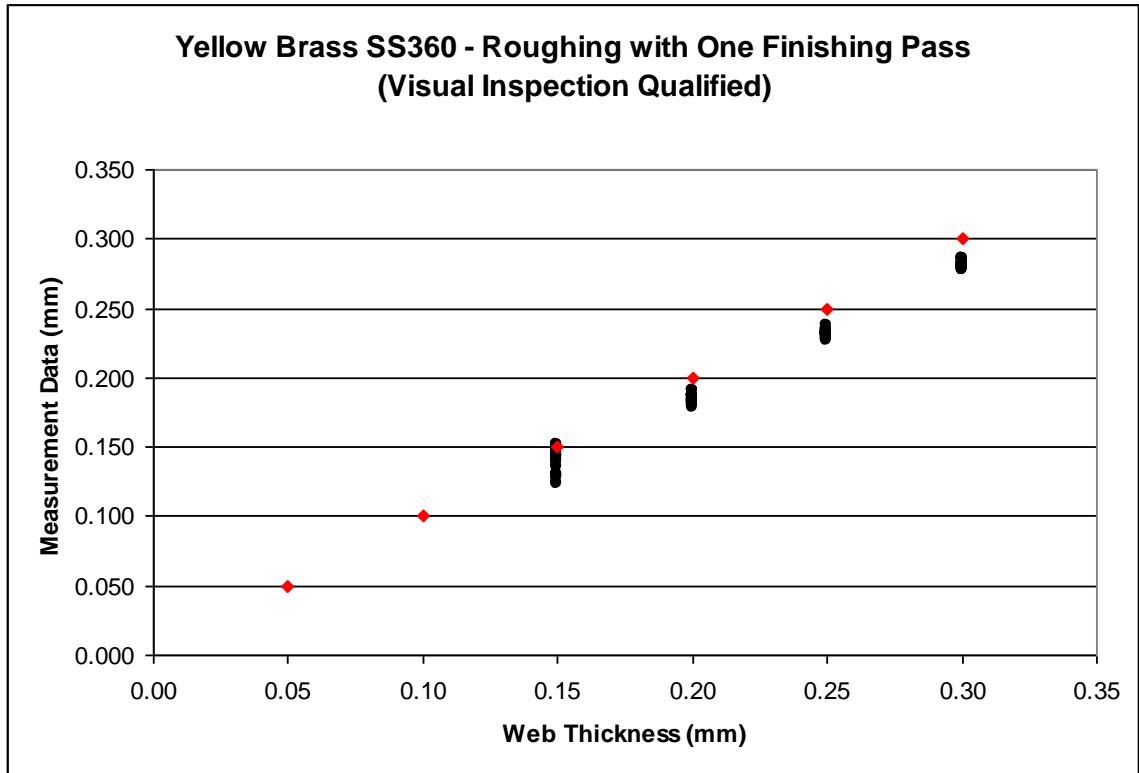

passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) and 0.10 millimeters (.004 inches) failed the visual inspection test, so there are no data points represented at these thicknesses. Also, several of the 0.15 millimeter (.006 inch) sections failed the visual inspection test thus reducing the number of data points indicated at that thickness.

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.6. The mean for each data set is smaller than the respective target value. The ANOVA test indicated that this data is statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

**Table 4.6** - Yellow Brass SS360 - Statistics for Roughing with No Finishing Passes Data Set

The ANOVA test further indicated that there was a significant difference in the data when the measurements that were taken from the tops of the thin-walled sections were compared to those taken from the bottoms of the sections. A t-value of less than 0.0001 was observed.

Figure 4.29 is a graph depicting the accuracy of cutting thin-walled sections from Yellow Brass SS360 while utilizing the three cutting parameters previously specified. Each of the calculated mean values for the respective target thicknesses and cutting parameters were subtracted from the target value in order to generate the values represented on this graph. This effectually makes 0.00 the target. Upper and lower specification limits were also indicated at  $\pm 0.005$  millimeters. The accuracy obtainable by each of the cutting parameters can be readily seen along with a comparison of the cutting parameters.

**Figure 4.29** - Yellow Brass SS360 - Accuracy in Cutting Thin-walled Sections (mean minus target)

A second ANOVA test was performed in order to determine the statistical significance between cutting parameters when machining the same material type. Table 4.9 lists the P-values that were generated from the ANOVA test. Any P-value which is greater than 0.05 indicates that there is not a statistically significant difference between the data sets being compared. Therefore, there is no statistical difference between the data obtained when comparing any of the cutting parameters utilized for any of the section target thicknesses when cutting Yellow Brass SS360.

**Table 4.9** - Yellow Brass SS360 - P-values of Comparisons between Cutting Parameters

Target Thickness	No Finishing to One Finishing	No Finishing to Three Finishing	One Finishing to Three Finishing
0.30	0.6421421453	0.4868496955	0.7342283808
0.25	0.6413974068	0.4966835251	0.7474713961

0.10	-	-	-
0.05	-	-	-

Figure 4.30 is a graph of the calculated P-values for the comparisons between cutting parameters while machining Yellow Brass SS360. None of the P-values are located below the line indicating statistical significance. Therefore, statistically speaking,

**Figure 4.30** - Yellow Brass SS360 – Statistical Significance Comparison of Cutting Parameters by P-values

there exists no significant difference between the data sets generated by the three different cutting parameters used in this study.

A third ANOVA test was performed on each data set of a thin-walled section according to the number of finishing passes that were utilized in order to compare the effect of material type. This test generated a P-value which indicates if there is a statistically significant difference between the data sets of the five different materials.

Table 4.10 lists all of the P-values obtained through the ANOVA test in comparing the data sets for Yellow Brass SS360 to the data sets for the other four materials.

**Table 4.10** - P-values Indicating Statistical Significance between Yellow Brass SS360 and ...

	0.05	-	-	-	-

A graph depicting the relationships between each of the P-values can be seen in Figure 4.31. Included in this graph is a pink line with a P-value of 0.05. Any of the values above this line indicate that there is no statistical difference between the data sets

Figure 4.31 - Statistical Significance of Yellow Brass SS360 to the Other Four Materials

while all of the values located below the line demonstrate that there is a statistical difference between the data sets.

When utilizing the machining parameters of a roughing with no finishing passes it can be seen that there is a statistically significant difference between the data sets with section target thicknesses of 0.30 and 0.25 millimeters (.012 and .010 inches) when comparing Yellow Brass SS360 to the remainder of the materials. When the section target thickness was 0.20 millimeters (.008 inches) the data sets for both the Aluminum 6061 T6 and the D2 Tool Steel at 25 to 30 RC demonstrated statistical significance while the data sets for the 420 Stainless Steel and the D2 Tool Steel at 60 to 65 RC did not demonstrate statistical significance. None of the data sets for any of the materials

demonstrated statistical significance when the section target thickness was 0.15 millimeters (.006 inches).

When utilizing the machining parameters of a roughing with one finishing pass the data sets for all of the materials demonstrated statistical significance for the section target thicknesses of 0.30, 0.25, and 0.20 millimeters (.012, .010, and .008 inches) while none of the data sets for all of the materials were not statistically significant for the sections with a target thickness of 0.15 millimeters (.006 inches).

When utilizing the machining parameters of a roughing with three finishing passes the data sets for all of the materials demonstrated statistical significance.

#### **4.3.3 420 Stainless Steel – Statistical Analysis**

Figure 4.32 indicates the data set that was used in the statistical analysis for 420 Stainless Steel while utilizing cutting parameters of a roughing with no finishing passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness. Also, several of the 0.10 millimeter (.004 inch) sections failed the visual inspection test thus reducing the number of data points indicated at that thickness.

**Figure 4.32** - Data Set Used for 420 Stainless Steel - Roughing with No Finishing Passes

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.11. The mean for each data set is smaller than the respective target value and very consistent to the others in this group.

**Table 4.11** - 420 Stainless Steel - Statistics for Roughing with No Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.282	-0.018	0.002973	3.3634	1.3018
0.250	0.232	-0.018	0.003254	3.0732	1.1951

0.100	0.090	-0.010	0.011886	0.8413	0.5609
0.050	-	-	-	-	-

Figure 4.34 indicates the data set that was used in the statistical analysis for 420 Stainless Steel while utilizing cutting parameters of a roughing with three finishing passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness.

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.13. The mean for each data set except that with a target of 0.25 millimeters (.010 inches) is larger than the respective target value. The mean of the data set with a target thickness of 0.25 millimeters (.010 inches) is less than that target value. The ANOVA test indicated that this data is not statistically significant from the target values and has a combined t-value of 0.2922 for the specified parameters.

Figure 4.34 - Data Set Used for 420 Stainless Steel - Roughing with Three Finishing Passes

0.050	-	-	-	-	-

The ANOVA test further indicated that there was a significant difference in the data when the measurements that were taken from the tops of the thin-walled sections were compared to those taken from the bottoms of the sections. A t-value of less than 0.0001 was observed.

Figure 4.35 is a graph depicting the accuracy of cutting thin-walled sections from 420 Stainless Steel while utilizing the three cutting parameters previously specified. Each of the calculated mean values for the respective target thicknesses and cutting parameters were subtracted from the target value in order to generate the values represented on this graph. This effectually makes 0.00 the target. Upper and lower specification limits were also indicated at  $\pm 0.005$  millimeters. The accuracy obtainable by each of the cutting parameters can be readily seen along with a comparison of the cutting parameters.

**Figure 4.35** - 420 Stainless Steel - Accuracy in Cutting Thin-walled Sections (mean minus target)

A second ANOVA test was performed in order to determine the statistical significance between cutting parameters when machining the same material type. Table

4.14 lists the P-values that were generated from the ANOVA test. Any P-value which is greater than 0.05 indicates that there is not a statistically significant difference between the data sets being compared. Therefore, there is no statistical difference between the data obtained when comparing any of the cutting parameters utilized for any of the section target thicknesses when cutting 420 Stainless Steel.

**Table 4.14** - 420 Stainless Steel - P-values of Comparisons between Cutting Parameters

Target Thickness	No Finishing to One Finishing	No Finishing to Three Finishing	One Finishing to Three Finishing
0.30	0.5266018304	0.4034056519	0.7148576019
0.25	0.5548510289	0.4269103403	0.7266468512

0.05	-	-	-

Figure 4.36 is a graph of the calculated P-values for the comparisons between cutting parameters while machining 420 Stainless Steel. None of the P-values are located below the line indicating statistical significance. Therefore, statistically speaking, there exists no significant difference between the data sets generated by the three different cutting parameters used in this study.

A third ANOVA test was performed on each data set of a thin-walled section according to the number of finishing passes that were utilized in order to compare the effect of material type. This test generated a P-value which indicates if there is a statistically significant difference between the data sets of the five different materials. Table 4.15 lists all of the P-values obtained through the ANOVA test in comparing the data sets for 420 Stainless Steel to the data sets for the other four materials.

A graph depicting the relationships between each of the P-values can be seen in Figure 4.37. Included in this graph is a pink line with a P-value of 0.05. Any of the values above this line indicate that there is no statistical difference between the data sets while all of the values located below the line demonstrate that there is a statistical difference between the data sets.

Figure 4.37 - Statistical Significance for 420 Stainless Steel to the Other Four Materials

In comparing the data sets for the 420 Stainless Steel, while utilizing the machining parameters of a roughing with no finishing passes, with the data sets for the Aluminum 6061 T6 it can be seen that there is a statistically significant difference between them when cutting sections with target thicknesses of 0.30, 0.25, and 0.20 millimeters (.012, .010, and .008 inches), but there is no significant statistical difference

for the sections with a target thickness of 0.15 millimeters (.006 inches). A comparison with the Yellow Brass SS360 demonstrates a statistical difference for the sections with target thicknesses of 0.30 and 0.25 millimeters (.012 and .010 inches), but no statistically significant difference for the sections with target thicknesses of 0.20 and 0.15 millimeters (.008 and .006 inches). In comparing the D2 Tool Steel at 25 to 30 RC statistical significance was observed for the sections with target thicknesses of 0.25, 0.20, and 0.15 millimeters (.010, .008, and .006 inches), but there was no statistical significance observed for the sections with target thicknesses of 0.30 and 0.10 millimeters (.012 and .004 inches). There was no statistical significance observed between any of the data sets when compared with the D2 Tool Steel at 60 to 65 RC.

When utilizing the machining parameters of a roughing with one finishing pass there was no statistical significance observed when comparing the data sets for 420 Stainless Steel to those of the D2 Tool Steel at 25 to 30 RC and the D2 Tool Steel at 60 to 65 RC. When compared with the Aluminum 6061 T6 none of the data sets demonstrated statistical significance except those for the section with a target thickness of 0.10 millimeters (.004 inches). A comparison with the data sets for Yellow Brass SS360 demonstrated a statistical significance for all of the section thicknesses except that with a target thickness of 0.15 millimeters (.006 inches).

In comparing the data sets for the 420 Stainless Steel, when utilizing the machining parameters of a roughing with three finishing passes, with those of the Aluminum 6061 T6 it was observed that there was a statistical significance for all of the section thicknesses except that with a target thickness of 0.10 millimeters (.004 inches). All of the data sets for the Yellow Brass SS360 demonstrated a statistical significance. A

comparison with the data sets for the D2 Tool Steel at 25 to 30 RC showed a statistical significance for those with target thicknesses of 0.25 and 0.20 millimeters (.010 and .008 inches), while there was no statistical significance observed for the sections with target thicknesses of 0.30, 0.15, and 0.10 millimeters (.012, .006, and .004 inches). When compared with the data sets for the D2 Tool Steel at 60 to 65 RC there was no statistical significance found.

#### 4.3.4 D2 Tool Steel 25-30 RC – Statistical Analysis

Figure 4.38 indicates the data set that was used in the statistical analysis for D2 Tool Steel at 25 to 30 RC while utilizing cutting parameters of a roughing with no finishing passes. All of the thin-walled sections which had a target thickness of 0.05

Figure 4.38 - Data Set Used for D2 Tool Steel 25-30 RC - Roughing with No Finishing Passes

millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness. Also, several of the 0.10 millimeter (.004 inch) sections failed the visual inspection test thus reducing the number of data points indicated at that thickness.

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.16. The mean for each data set is smaller than the respective target value. The ANOVA test indicated that this data is statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

**Table 4.16** - D2 Tool Steel 25-30 RC - Statistics for Roughing with No Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$

0.150	0.141	-0.009	0.004937	2.0257	1.3917
0.100	0.094	-0.006	0.010270	0.9737	0.7717
0.050	-	-	-	-	-

The ANOVA test indicated that this data is statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

Figure 4.40 indicates the data set that was used in the statistical analysis for D2 Tool Steel at 25 to 30 RC while utilizing cutting parameters of a roughing with three finishing passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness.

**Figure 4.40** - Data Set Used for D2 Tool Steel 25-30 RC - Roughing with Three Finishing Passes

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.18. The mean for each data set except that with a target value of 0.10 millimeters (.004 inches) is larger than the

**Table 4.18** - D2 Tool Steel 25-30 RC - Statistics for Roughing with Three Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.301	0.001	0.003090	3.2366	3.1707
0.250	0.251	0.001	0.001183	8.4555	8.1423
0.200	0.203	0.003	0.001249	8.0094	7.1640
0.150	0.152	0.002	0.001934	5.1696	4.8728
0.100	0.097	-0.003	0.007659	1.3057	1.1848
0.050	-	-	-	-	-

respective target value. The mean for the data set with a target value of 0.10 millimeters (.004 inches) is smaller than the target value. The ANOVA test indicated that this data is not statistically significant from the target values and has a combined t-value of 0.3465 for the specified parameters.

For the D2 Tool Steel at 25 to 30 RC, the ANOVA test indicated that, in contrast to the previous materials discussed, there was no significant difference in the data when the measurements that were taken from the tops of the thin-walled sections were compared to those taken from the bottoms of the sections. A t-value of 0.2261 was observed.

Figure 4.41 is a graph depicting the accuracy of cutting thin-walled sections from D2 Tool Steel at 25 to 30 RC while utilizing the three cutting parameters previously specified. Each of the calculated mean values for the respective target thicknesses and cutting parameters were subtracted from the target value in order to generate the values represented on this graph. This effectually makes 0.00 the target. Upper and lower specification limits were also indicated at  $\pm 0.005$  millimeters. The accuracy obtainable by each of the cutting parameters can be readily seen along with a comparison of the cutting parameters.

**Figure 4.41** - D2 Tool Steel 25-30 RC - Accuracy in Cutting Thin-walled Sections (mean minus target)

A second ANOVA test was performed in order to determine the statistical significance between cutting parameters when machining the same material type. Table 4.19 lists the P-values that were generated from the ANOVA test. Any P-value which is greater than 0.05 indicates that there is not a statistically significant difference between

**Table 4.19** - D2 Tool Steel 25-30 RC - P-values of Comparisons between Cutting Parameters

Target Thickness	No Finishing to One Finishing	No Finishing to Three Finishing	One Finishing to Three Finishing
0.30	0.5185476356	0.3934144598	0.7088139305
0.25	0.5121146184	0.3912289610	0.7141800778

0.10	0.8624544080	0.7123463043	0.7615375244
0.05	-	-	-

the data sets being compared. Therefore, there is no statistical difference between the data obtained when comparing any of the cutting parameters utilized for any of the section target thicknesses when cutting D2 Tool Steel at 25 to 30 RC.

Figure 4.42 is a graph of the calculated P-values for the comparisons between cutting parameters while machining D2 Tool Steel at 25 to 30 RC. None of the P-values are located below the line indicating statistical significance. Therefore, statistically speaking, there exists no significant difference between the data sets generated by the three different cutting parameters used in this study.

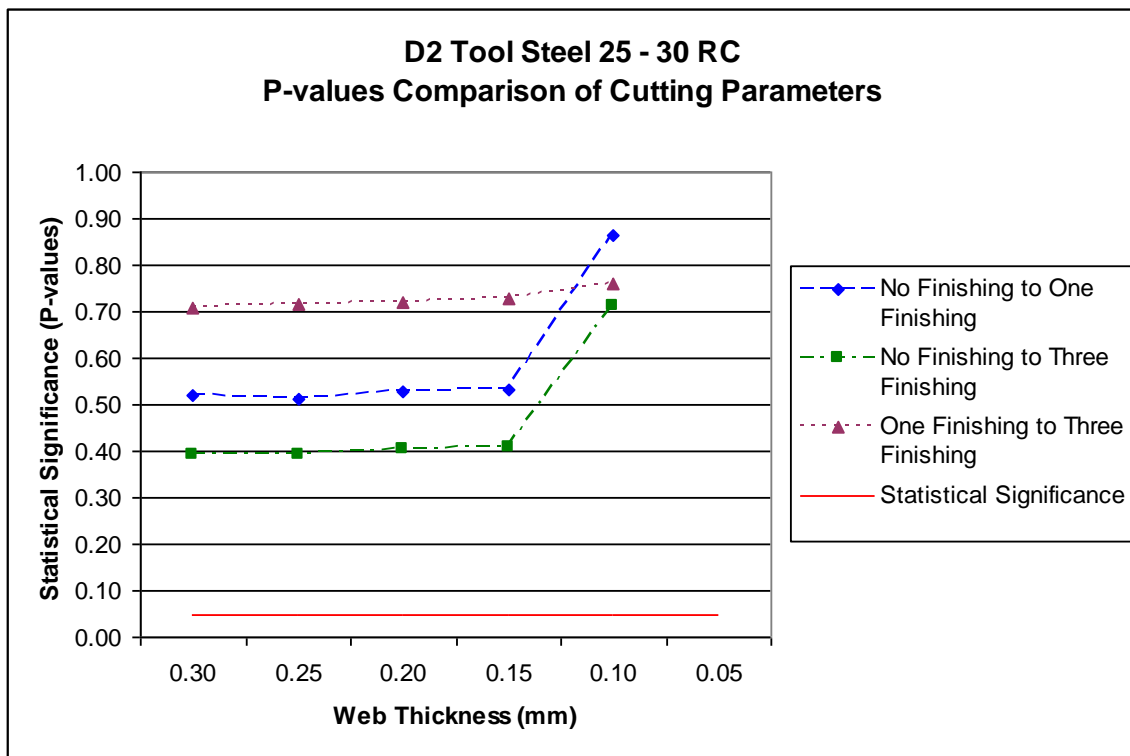

Figure 4.42 - D2 Tool Steel 25-30 RC – Statistical Significance Comparison of Cutting Parameters by P-values

A third ANOVA test was performed on each data set of a thin-walled section according to the number of finishing passes that were utilized in order to compare the effect of material type. This test generated a P-value which indicates if there is a statistically significant difference between the data sets of the five different materials. Table 4.20 lists all of the P-values obtained through the ANOVA test in comparing the data sets for D2 Tool Steel at 25 to 30 RC to the data sets for the other four materials.

**Table 4.20** - P-values Indicating Statistical Significance between D2 Tool Steel at 25 - 30 RC and ...

	0.05	-	-	-	-

A graph depicting the relationships between each of the P-values can be seen in Figure 4.43. Included in this graph is a pink line with a P-value of 0.05. Any of the values above this line indicate that there is no statistical difference between the data sets while all of the values located below the line demonstrate that there is a statistical difference between the data sets.

Figure 4.43 - Statistical Significance of D2 Tool Steel at 25 - 30 RC to the Other Four Materials

In comparing the data sets for the D2 Tool Steel at 25 to 30 RC, while utilizing the machining parameters of a roughing with no finishing passes, with the data sets for the Aluminum 6061 T6 it can be seen that there is not a statistically significant difference for any of the sections. In a comparison with the data sets for the Yellow Brass SS360 it was observed that there is a statistical difference for the sections with target thicknesses of 0.30, 0.25, and 0.20 millimeters (.012, .010, and .008 inches), but there is not a statistically significant difference for the data sets with a target thickness of 0.15 millimeters (.006 inches). The data sets for the 420 Stainless Steel are statistically significant for the section target thicknesses of 0.25, 0.20, and 0.15 millimeters (.010, .008, and .006 inches), but they are not statistically different for the section target thicknesses of 0.30 and 0.10 millimeters (.012 and .004 inches). In comparison with the

data sets for the D2 Tool Steel at 60 to 65 RC it was observed that there was a statistically significant difference for the sections with target thicknesses of 0.30, 0.25, 0.20, and 0.15 millimeters (.012, .010, .008, and .006 inches), but they are not statistically different for the section target thickness of 0.10 millimeters (.004 inches).

When utilizing the machining parameters of a roughing with one finishing pass, it was observed that the majority of the comparisons with the D2 Tool Steel at 25 to 30 RC were not statistically significant. The data sets for the Yellow Brass SS360 were the only ones that demonstrated statistical significance when the section target thicknesses were 0.30 and 0.25 millimeters (.012 and .010 inches). A comparison with the data sets for the section target thickness of 0.20 millimeters (.008 inches) revealed that Yellow Brass SS360 and D2 Tool Steel at 60 to 65 RC demonstrated statistical significance. A comparison with the data sets for the section target thickness of 0.10 millimeters (.004 inches) revealed that Aluminum 6061 T6 and D2 Tool Steel at 60 to 65 RC demonstrated statistical significance.

In comparing the data sets for the D2 Tool Steel at 25 to 30 RC, while utilizing the machining parameters of a roughing with three finishing passes, with the data sets for the Aluminum 6061 T6 it can be seen that there is a statistically significant difference when cutting sections with target thicknesses of 0.30 and 0.15 millimeters (.012 and .006 inches), but there is no significant statistical difference for the sections with target thicknesses of 0.25, 0.20, and 0.10 millimeters (.010, .008, and .004 inches). A comparison with the Yellow Brass SS360 demonstrates a statistical difference for all of the data sets. In comparing the 420 Stainless Steel statistical significance was observed for the sections with target thicknesses of 0.25 and 0.20 millimeters (.010 and .008

inches), but there was no statistical significance observed for the sections with target thicknesses of 0.30, 0.15, and 0.10 millimeters (.012, .006, and .004 inches). In comparing the data sets with those of the D2 Tool Steel at 60 to 65 RC it was observed that there was a statistically significant difference for those with target thicknesses of 0.25, 0.20, and 0.15 millimeters (.010, .008, and .006 inches), but there was no statistically significant difference for those sections with target thicknesses of 0.30 and 0.10 millimeters (.012 and .004 inches).

#### 4.3.5 D2 Tool Steel 60-65 RC – Statistical Analysis

Figure 4.44 indicates the data set that was used in the statistical analysis for D2 Tool Steel at 60 to 65 RC while utilizing cutting parameters of a roughing with no

Figure 4.44 - Data Set Used for D2 Tool Steel 60-65 RC - Roughing with No Finishing Passes

finishing passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness. Also, several of the 0.10 millimeter (.004 inch) sections failed the visual inspection test thus reducing the number of data points indicated at that thickness.

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.21. The mean for each data set is smaller than the respective target value. The ANOVA test indicated that this data is statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

**Table 4.21** - D2 Tool Steel 60-65 RC - Statistics for Roughing with No Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$

0.050	-	-	-	-	-

Figure 4.45 indicates the data set that was used in the statistical analysis for D2 Tool Steel at 60 to 65 RC while utilizing cutting parameters of a roughing with one finishing pass. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness.

**Figure 4.45** - Data Set Used for D2 Tool Steel 60-65 RC - Roughing with One Finishing Pass

The arithmetic mean, mean’s difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.22. The mean for each data set is smaller than the respective target value. The ANOVA test indicated that this data is

**Table 4.22** - D2 Tool Steel 60-65 RC - Statistics for Roughing with One Finishing Pass Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.288	-0.012	0.007232	1.3828	0.8194
0.250	0.240	-0.010	0.003879	2.5781	1.7092
0.200	0.189	-0.011	0.004073	2.4553	1.5550
0.150	0.141	-0.010	0.004018	2.4886	1.7005
0.100	0.085	-0.015	0.009959	1.0041	0.4909
0.050	-	-	-	-	-

statistically significant from the target values and has a combined t-value of less than 0.0001 for the specified parameters.

Figure 4.46 indicates the data set that was used in the statistical analysis for D2 Tool Steel at 60 to 65 RC while utilizing cutting parameters of a roughing with three finishing passes. All of the thin-walled sections which had a target thickness of 0.05 millimeters (.002 inches) failed the visual inspection test, so there are no data points represented at this thickness.

**Figure 4.46** - Data Set Used for D2 Tool Steel 60-65 RC - Roughing with Three Finishing Passes

The arithmetic mean, mean's difference from target, standard deviation,  $C_p$ , and  $C_{pk}$  for each data set indicated above is shown in Table 4.23. The mean for the data sets with target values of 0.30 and 0.200 millimeters (.012 and .008 inches) are larger than the

**Table 4.23** - D2 Tool Steel 60-65 RC - Statistics for Roughing with Three Finishing Passes Data Set

Web Thickness (mm)	Mean (mm)	$\mu$ - Target Thickness (mm)	Standard Deviation	$C_p$	$C_{pk}$
0.300	0.301	0.001	0.001589	6.2917	6.0704
0.250	0.249	-0.001	0.001609	6.2158	6.0086
0.200	0.201	0.001	0.001629	6.1388	5.9796
0.150	0.150	0.000	0.001328	7.5277	7.4441
0.100	0.098	-0.002	0.005626	1.7776	1.6788
0.050	-	-	-	-	-

respective target value. The mean for the data sets with target values of 0.25 and 0.10 millimeters (.010 and .004 inches) are smaller than their respective target value while the mean for the data set with a target value of 0.15 millimeters (.006 inches) is equal to the target value. The ANOVA test indicated that this data is not statistically significant from the target values and has a combined t-value of 0.8441 for the specified parameters.

For the D2 Tool Steel at 60 to 65 RC, the ANOVA test indicated that, in contrast to the first three materials discussed yet equivalent to the D2 Tool Steel as 35 to 30 RC, there was no significant difference in the data when the measurements that were taken from the tops of the thin-walled sections were compared to those taken from the bottoms of the sections. A t-value of 0.4404 was observed.

Figure 4.47 is a graph depicting the accuracy of cutting thin-walled sections from D2 Tool Steel at 60 to 65 RC while utilizing the three cutting parameters previously specified. Each of the calculated mean values for the respective target thicknesses and cutting parameters were subtracted from the target value in order to generate the values represented on this graph. This effectually makes 0.00 the target. Upper and lower specification limits were also indicated at  $\pm 0.005$  millimeters. The accuracy obtainable

**Figure 4.47** - D2 Tool Steel 60-65 RC - Accuracy in Cutting Thin-walled Sections (mean minus target)

by each of the cutting parameters can be readily seen along with a comparison of the cutting parameters.

A second ANOVA test was performed in order to determine the statistical significance between cutting parameters when machining the same material type. Table 4.24 lists the P-values that were generated from the ANOVA test. Any P-value which is greater than 0.05 indicates that there is not a statistically significant difference between the data sets being compared. Therefore, there is no statistical difference between the data obtained when comparing any of the cutting parameters utilized for any of the section target thicknesses when cutting D2 Tool Steel at 60 to 65 RC.

**Table 4.24** - D2 Tool Steel 60-65 RC - P-values of Comparisons between Cutting Parameters

Target Thickness	No Finishing to One Finishing	No Finishing to Three Finishing	One Finishing to Three Finishing
0.30	0.5569437666	0.4076369144	0.7005773010
0.25	0.5486871300	0.4206432641	0.7236164208
0.20	0.5842338658	0.4336260607	0.7183390700

0.05	-	-	-

Figure 4.48 is a graph of the calculated P-values for the comparisons between cutting parameters while machining D2 Tool Steel at 60 to 65 RC. None of the P-values are located below the line indicating statistical significance. Therefore, statistically,

**Figure 4.48** - D2 Tool Steel 60-65 RC – Statistical Significance Comparison of Cutting Parameters by P-values

there exists no significant difference between the data sets generated by the three different cutting parameters used in this study.

A third ANOVA test was performed on each data set of a thin-walled section according to the number of finishing passes that were utilized in order to compare the effect of material type. This test generated a P-value which indicates if there is a statistically significant difference between the data sets of the five different materials. Table 4.25 lists all of the P-values obtained through the ANOVA test in comparing the data sets for D2 Tool Steel at 60 to 65 RC to the data sets for the other four materials.

	0.05	-	-	-	-

A graph depicting the relationships between each of the P-values can be seen in Figure 4.49. Included in this graph is a pink line with a P-value of 0.05. Any of the values above this line indicate that there is no statistical difference between the data sets

Figure 4.49 - Statistical Significance of D2 Tool Steel at 60 - 65 RC to the Other Four Materials

while all of the values located below the line demonstrate that there is a statistical difference between the data sets.

In comparing the data sets for the D2 Tool Steel at 60 to 65 RC, while utilizing the machining parameters of a roughing with no finishing passes, with the data sets for the 420 Stainless Steel it was observed that there was not a statistically significant difference for any of the sections, but a comparison with the remainder of the materials demonstrated statistical significance with the majority of these data sets. The exceptions to this being the Yellow Brass SS360 with section target thicknesses of 0.20 and 0.15 millimeters (.008 and .006 inches), and the D2 Tool Steel at 25 to 30 RC with a section target thickness of 0.10 millimeters (.004 inches).

In comparing the data sets for the D2 Tool Steel at 60 to 65 RC, when utilizing the machining parameters of a roughing with one finishing pass, it was observed that the data sets for the Yellow Brass SS360 were the only ones that demonstrated statistical significance for the sections with target thicknesses of 0.30 and 0.25 millimeters (.012 and .010 inches). A comparison of the data sets for the section target thickness of 0.20 millimeters (.008 inches) demonstrated that all of the material except 420 Stainless Steel were statistically significant. None of the data sets for any of the materials were statistically significant for the section target thickness of 0.15 millimeters (.006 inches). A comparison of the data sets for the section target thickness of 0.10 millimeters (.004 inches) demonstrated that the Aluminum 6061 T6 and the D2 Tool Steel at 25 to 30 RC were statistically significant while the 420 Stainless Steel was not statistically significant.

In comparing the data sets for the D2 Tool Steel at 60 to 65 RC, when utilizing the machining parameters of a roughing with three finishing passes, with those of the Aluminum 6061 T6 it was observed that there was a statistical significance for all of the section thicknesses except that with a target thickness of 0.10 millimeters (.004 inches). All of the data sets for the Yellow Brass SS360 demonstrated a statistical significance. When compared with the data sets for the 420 Stainless Steel there was no statistical significance found. A comparison with the data sets for the D2 Tool Steel at 25 to 30 RC showed a statistical significance for those with target thicknesses of 0.25, 0.20, and 0.15 millimeters (.010, .008, and .006 inches), while there was no statistical significance observed for the sections with target thicknesses of 0.30 and 0.10 millimeters (.012 and .004 inches).

#### 4.4 Statistical Comparisons of the Data Distribution Between Materials

As discussed in the introduction to this section, a  $C_p$  and  $C_{pk}$  value was calculated for each data set using a common set of specification limits so that comparisons and trends for the data distribution could be evaluated between the five materials tested in this experiment. These comparisons were separated into a trichotomy according to the number of finishing passes used.

Table 4.26 is a compilation of all the calculated  $C_p$  and  $C_{pk}$  values for the five different materials studied while utilizing cutting parameters of a roughing with no finishing passes. These values are delineated by material type and by the thin-walled section target thickness.

**Table 4.26** -  $C_p$  and  $C_{pk}$  Comparisons while Utilizing a Roughing with No Finishing Passes

Web Thickness	Aluminum 6061 T6	Yellow Brass SS360	420 Stainless Steel	D2 Tool Steel 25-30 RC	D2 Tool Steel 60-65 RC	
$C_p$	0.300	1.2139	1.2212	3.3634	1.2464	2.7641

materials shown can be observed with the size of the distribution decreasing as the numbers on the y-axis increase.

In comparing these values to those obtained while utilizing a roughing pass with no finishing passes there were slight change observed for both the Aluminum 6061 T6 and the D2 Tool Steel at 60 to 65 RC, but there were no noticeable trends. There is a significant increase in the capability for the Yellow Brass SS360. The D2 Tool Steel at 25 to 30 RC demonstrated a slight increase over all of the values while the 420 Stainless Steel demonstrated a significant decrease in capability.

Table 4.28 is a compilation of all the calculated  $C_p$  and  $C_{pk}$  values for the five different materials studied while utilizing cutting parameters of a roughing with three finishing passes.

**Table 4.28** -  $C_p$  and  $C_{pk}$  Comparisons while Utilizing a Roughing with Three Finishing Passes

Figure 4.52 is a graph depicting the  $C_p$  and  $C_{pk}$  values that are listed in the previous table and illustrate the data with the independent variable being the material types. The size of the distribution of each data set as it relates to those of the other materials shown can be observed with the size of the distribution decreasing as the numbers on the y-axis increase.

**Figure 4.52** –  $C_p$  and  $C_{pk}$  Values Depicting the Data Distributions while Utilizing a Roughing with Three Finishing Passes

With the exception of the Yellow Brass SS360, all of the materials demonstrated an overall improvement in both capability and accuracy when utilizing a roughing with three finishing passes. The Yellow Brass SS360 demonstrated similar values to those seen when utilizing a roughing with no finishing passes.

## **5 Conclusions and Recommendations**

### **5.1 Introduction**

Wire Electric Discharge Machining (wire-EDM) is a nontraditional manufacturing process which uses successive sparks to vaporize a kerf in a workpiece. The path along which the machine cuts is programmed and uploaded into the CNC machine. In wire-EDM, a wire is used as the agent in order to position the sparks in the desired area. This wire is typically brass, an alloy of copper and zinc. A dielectric fluid, typically deionized water, is used to help control the spark gap by: creating a controllable electrical barrier, flushing away contaminants in the kerf, and creating a temperature controlled environment. Modern machines use linear motors to move the wire along the desired cut path described by the NC code.

Although this process is relatively new, it is being used extensively in the industrial sector. The process has improved dramatically throughout its existence, but very little research has been performed in cutting thin-walled sections utilizing the default parameters of a conventional wire-EDM machine.

### **5.2 Hypothesis**

The purpose of this study was to observe the limitations in cutting thin-walled sections, which are constrained on each end, from five different commonly used metals with a conventional wire-EDM machine while utilizing the machine's default settings for

different combinations of the roughing and finishing passes. The null hypothesis for this study states that there is no significant difference of wire-EDM cutting performance of thin-walled sections in five different commonly used metals while utilizing a variation of the rough and finishing parameters of the Sodick AQ325L wire-EDM machine.

### **5.3 Conclusions**

The data obtained from this study was first separated according to material type and comparisons were made between the three sets of cutting parameters, and second according to cutting parameters so that comparisons could be made between the five metals. The test specimens were analyzed by two different methods – visual inspection and measurements of the thin-walled sections with a CMM in order to test accuracy. ANOVA tests were also performed in order to determine if there were statistically significant differences between the data sets being compared. Conclusions were drawn from this data in order to reject or fail to reject the null hypothesis.

In comparing the results of this study to those obtained by Kim in his thesis *Determination of Wall Thickness and Height Limits when Cutting Various Materials with Wire Electric Discharge Machining Process* it was observed that both the accuracy and number of defect free parts was greater in this study. This is attributed to each of the thin-walled sections being constrained on both ends as opposed to only being constrained on one end.

### **5.3.1 Aluminum 6061 T6 – Visual and Statistical Conclusions**

The analysis indicates that differences exist between the respective data sets obtained when utilizing the three sets of cutting parameters specified in Chapter 3. Due to these differences, which are discussed below, the null hypothesis was rejected as it relates to the comparison of these cutting parameters while machining Aluminum 6061 T6.

When machining Aluminum 6061 T6 with the cutting parameters of a roughing with no finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.25 millimeters (.010 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.027 millimeters (.0011 inches) under target to 0.024 millimeters (.0009 inches) under target.

When machining Aluminum 6061 T6 with the cutting parameters of a roughing with one finishing pass the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.20 millimeters (.008 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.010 millimeters (.0004 inches) under target to 0.004 millimeters (.0002 inches) under target.

When machining Aluminum 6061 T6 with the cutting parameters of a roughing with three finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.15 millimeters (.006 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.003 millimeters (.0001 inches) over target to 0.011 millimeters (.0004 inches) over target.

### **5.3.2 Yellow Brass SS360 – Visual and Statistical Conclusions**

The analysis indicates that the only differences that exist are when a comparison is made to the data obtained when utilizing the cutting parameters of a roughing with no finishing passes. Due to the observed differences, which are discussed below, the null hypothesis was rejected as it relates to comparisons with the cutting parameter of a roughing with no finishing passes, but the data failed to reject the null hypothesis for comparisons between the two remaining cutting parameters while machining Yellow Brass SS360.

When machining Yellow Brass SS360 with the cutting parameters of a roughing with no finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.20 millimeters (.008 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.014 millimeters (.0006 inches) under target to 0.012 millimeters (.0005 inches) under target.

When machining Yellow Brass SS360 with the cutting parameters of a roughing with one finishing pass the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.15 millimeters (.006 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.019 millimeters (.0007 inches) under target to 0.011 millimeters (.0004 inches) under target.

When machining Yellow Brass SS360 with the cutting parameters of a roughing with three finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.15 millimeters (.006 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.015 millimeters (.0006 inches) under target to 0.012 millimeters (.0005 inches) under target.

### **5.3.3 420 Stainless Steel – Visual and Statistical Conclusions**

The analysis indicates that differences exist between the respective data sets obtained when utilizing the three sets of cutting parameters specified in Chapter 3. Due to these differences, which are discussed below, the null hypothesis was rejected as it relates to the comparison of these cutting parameters while machining 420 Stainless Steel.

When machining 420 Stainless Steel with the cutting parameters of a roughing with no finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.20 millimeters (.008 inches) without any defects, but some of the sections cut to a thickness of 0.15 millimeters (.006 inches) were also free of defects.

- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.018 millimeters (.0007 inches) under target to 0.016 millimeters (.0006 inches) under target.

When machining 420 Stainless Steel with the cutting parameters of a roughing with one finishing pass the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.15 millimeters (.006 inches) without any defects, but some of the sections cut to a thickness of 0.10 millimeters (.004 inches) were also free of defects.
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.010 millimeters (.0004 inches) under target to 0.007 millimeters (.0003 inches) under target.

When machining 420 Stainless Steel with the cutting parameters of a roughing with three finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.10 millimeters (.004 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.002 millimeters (.0001 inches) under target to 0.003 millimeters (.0001 inches) over target.

#### **5.3.4 D2 Tool Steel at 25 to 30 RC – Visual and Statistical Conclusions**

The analysis indicates that differences exist between the respective data sets obtained when utilizing the three sets of cutting parameters specified in Chapter 3. Due to these differences, which are discussed below, the null hypothesis was rejected as it

relates to the comparison of these cutting parameters while machining D2 Tool Steel at 25 to 30 RC.

When machining D2 Tool Steel at 25 to 30 RC with the cutting parameters of a roughing with no finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.15 millimeters (.006 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.026 millimeters (.0010 inches) under target to 0.022 millimeters (.0009 inches) under target.

When machining D2 Tool Steel at 25 to 30 RC with the cutting parameters of a roughing with one finishing pass the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.10 millimeters (.004 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.011 millimeters (.0004 inches) under target to 0.006 millimeters (.0002 inches) under target.

When machining D2 Tool Steel at 25 to 30 RC with the cutting parameters of a roughing with three finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.10 millimeters (.004 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.003 millimeters (.0001 inches) under target to 0.003 millimeters (.0001 inches) over target.

### **5.3.5 D2 Tool Steel at 60 to 65 RC – Visual and Statistical Conclusions**

The analysis indicates that differences exist between the respective data sets obtained when utilizing the three sets of cutting parameters specified in Chapter 3. Due to these differences, which are discussed below, the null hypothesis was rejected as it relates to the comparison of these cutting parameters while machining D2 Tool Steel at 60 to 65 RC.

When machining D2 Tool Steel at 60 to 65 RC with the cutting parameters of a roughing with no finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.15 millimeters (.006 inches) without any defects, but some of the sections cut to a thickness of 0.10 millimeters (.004 inches) were also free of defects.
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.019 millimeters (.0007 inches) under target to 0.016 millimeters (.0006 inches) under target.

When machining D2 Tool Steel at 60 to 65 RC with the cutting parameters of a roughing with one finishing pass the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.10 millimeters (.004 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.015 millimeters (.0006 inches) under target to 0.010 millimeters (.0004 inches) under target.

When machining D2 Tool Steel at 60 to 65 RC with the cutting parameters of a roughing with three finishing passes the following observations were made:

- Thin-walled sections could be successfully cut to a thickness equal to and greater than 0.10 millimeters (.004 inches).
- The mean values of the data sets obtained from the thin-walled sections which passed the visual inspection ranged from 0.002 millimeters (.0001 inches) under target to 0.001 millimeters (.00004 inches) over target.

### **5.3.6 Roughing with No Finishing Passes – Visual and Statistical Conclusions**

The analysis indicates that differences exist between some of the data sets for the five metals when utilizing the cutting parameters of a roughing with no finishing passes. These differences were observed in both the visual inspection and the numerical data. Due to the differences in data the null hypothesis was rejected for the following materials when utilizing a roughing with no finishing passes:

- Aluminum 6061 T6
- Yellow Brass SS360
- D2 Tool Steel at 25 to 30 RC

The data failed to reject the null hypothesis due to the similarity of the data for the following materials when utilizing a roughing with no finishing passes:

- 420 Stainless Steel
- D2 Tool Steel at 60 to 65 RC

### **5.3.7 Roughing with One Finishing Pass – Visual and Statistical Conclusions**

The analysis indicates that differences exist between some of the data sets for the five metals when utilizing the cutting parameters of a roughing with one finishing pass.

These differences were observed in both the visual inspection and the numerical data.

Due to the differences in data the null hypothesis was rejected for the following materials when utilizing a roughing with one finishing pass:

- Aluminum 6061 T6
- Yellow Brass SS360
- 420 Stainless Steel

The data failed to reject the null hypothesis due to the similarity of the data for the following materials when utilizing a roughing with one finishing pass:

- D2 Tool Steel at 25 to 30 RC
- D2 Tool Steel at 60 to 65 RC

### **5.3.8 Roughing with Three Finishing Passes – Visual and Statistical Conclusions**

The analysis indicates that differences exist between some of the data sets for the five metals when utilizing the cutting parameters of a roughing with three finishing passes. These differences were observed in both the visual inspection and the numerical data. Due to the differences in data the null hypothesis was rejected for the following materials when utilizing a roughing with three finishing passes:

- Aluminum 6061 T6
- Yellow Brass SS360

The data failed to reject the null hypothesis due to the similarity of the data for the following materials when utilizing a roughing with three finishing passes:

- 420 Stainless Steel

- D2 Tool Steel at 25 to 30 RC
- D2 Tool Steel at 60 to 65 RC

#### **5.4 Recommendations for Further Study**

While performing the review of literature for this study and while performing the study itself there were several areas of further study that became apparent. Further study in these areas would enhance the research that has already been done and help to further the use and capabilities of wire-EDM. These areas for further study are presented below.

- Perform the study that has been documented in this thesis, but use coated EDM wire to perform the cutting. With the increased flushing capabilities of the coated EDM wire and the change in electrical conductivity, the results may be different from those obtained through the use of conventional brass EDM wire.
- We observed bending of the webs for all of the metals, but at different thicknesses of the thin-walled sections. In thin-walled sections where bending did not occur increase the length of the webs in order to observe if bending will occur with the thicker webs or if the webs will continue to be straight over longer distances.
- There may be some residual stresses that are introduced into webs due to the thermal effect of the EDM process. Webs could be cut as is described in this thesis after which one end of the web could be freed. The amount of deflection could then be measured. Tests would have to be run on the parent material in order to determine if there are any residual stresses in the materials prior to their being cut on the wire-EDM machine. The cutting direction of the wire-EDM

machine would be an important factor to consider throughout the experiment and its setup.

- During this study it was observed that both the severity and number of defects were greater on the bottoms of the thin-walled sections in comparison to those observed on the tops of the sections. The reason for this is unknown, so a study could be performed in order to determine the cause.
- There is an occurrence which is depicted in Figure 4.52; a chart comparing the  $C_p$  and  $C_{pk}$  values of the five materials tested when utilizing the cutting parameters of a roughing with three finishing passes. Both the D2 Tool Steel at 25 to 30 RC and the D2 Tool Steel at 60 to 65 RC show an improvement and subsequent decline in capability. The capability of the process being reflective of the spread of the data set and therefore described by the  $C_p$  and  $C_{pk}$  values. By contrast, the other three materials show a steady decline in capability starting at the thickest sections and proceeding to the thinnest. It is not known what causes this increase in capability, so a study should be performed in order to determine the cause of this increase in capability.

We hereby certify that the aluminum extrusion covered by this report has been inspected and tested in accordance with our standard sampling plan or the requirements of any specifications of the material described in this report. The material has been found to meet the applicable requirements described herein. The samples, representative of the material, met the composition limits and had the mechanical properties shown. Also, note that Mercury is not a normal contaminant in aluminum alloys. Neither Mercury nor any of its compounds are used in the manufacture of our extrusions. Made in the U.S.A.
