Abstract

This study examined sleep, self-efficacy, and confidence and their effect on performance. Cadets from an Army Reserve officer training corps (ROTC) program were surveyed about their sleep quality using the Pittsburgh Sleep Quality Index (PSQI), their fatigue using the Epworth Sleepiness Scale (ESS), their sleep quantity using the Rosenkind formula, their confidence using the competitive trait anxiety index (CTAI-2), their self-efficacy using a task specific questionnaire, and performance was measured via the Army physical fitness test (APFT). The data from each variable was analyzed through correlations and regressions. The results support the hypothesis of cadets who have poorer sleep quality are less efficacious in their abilities subsequently score lower on their Army Physical Fitness Test (APFT). Further research is suggested to explore the mediation effect of sleep quantity and quality on self-efficacy and performance.

Chapter I

Introduction and Literature Review

Every day the armed forces are in search of ways to get the upper hand on the enemy, to keep our borders safer, and to develop new ways to increase force readiness. Sleep problems and fatigue are common among those in the armed forces (Troxel et al., 2015). Sleep has been directly linked with fatigue (Lavidor, Weller, & Babkoff, 2003) and sleep is considered an effective counter measure against fatigue (Aaronson, Teel, Cassmeyer, Neuberger, Pallikkathayil, et al., 1999; Aaronson, Pallikkathayil, Crighton, 2003). While fatigue has been included as a physiological source of self-efficacy (Feltz, Short, & Sullivan, 2008), less attention has been devoted to the relationship between sleep and self-efficacy beliefs. Self-efficacy is defined as “beliefs in one’s abilities to organize and execute the courses of action required to product given attainments” (Bandura, 1997, p. 3). The purpose of this study was to examine sleep as a physiological source of self-efficacy and its relationship with performance in the armed forces. It was hypothesized that cadets who have poorer sleep quality would be less efficacious in their abilities and would score lower on their Army Physical Fitness Test (APFT). With lower quality of sleep, higher rates of fatigue will be present effecting the overall levels of self-efficacy which will reduce participant’s performance outcomes.

Higher levels of self-efficacy are associated with better performance and other positive outcomes (Bandura, 1997; Moritz, Feltz, Fahrback, & Mack, 2000). Bandura’s self-efficacy theory states that physiological states are a source of self-efficacy, together with performance accomplishments, vicarious experiences, verbal persuasion, emotional states and imaginal experiences (Bandura, 1977; Feltz et al. 2008). Compared to other sources of self-efficacy,

physiological states has not received much research attention. People cognitively appraise their physiological state (i.e., levels of strength, fitness, fatigue, pain, etc.) when forming efficacy judgments (Feltz et al., 2008). According to Bandura (1997), the impact of physiological states on efficacy beliefs will depend on things such as situational factors and the meaning given to them. For example, speakers who ascribe their sweating to temperature in a room will likely perform better than those who ascribe their sweating to nervousness and anxiety.

One of the most popular examples of physiological states used in sport and exercise settings is fatigue. Fatigue has been defined as feelings of tiredness, weakness, or exhaustion (Campbell, et al., 2017; Gibson, Baden, Lambert, 2003). A prevalence of 15-20 percent of people suffer from fatigue symptoms in the United States (Aliyu, 2007; Aritake, S., Kaneita, Y., Ohtsu, T., Uchiyama, M., 2014; Buchwald, 1995; Sharpe & Wilks, 2002). There are many performance outcomes associated with fatigue. For example, people who are fatigued will reach exhaustion faster when compared to those who are not fatigued (Marcora, Staiano, & Manning, 2009). Reaction time is slowed when an individual becomes fatigued (Sant'Ana, Franchini, & Diefenthaler, 2016; Williamson & Feyer 2000) and decision making is inhibited (Harrison & Horne, 2000; Williamson & Feyer 2000). In sport situations, soccer in particular, people are less accurate with shot placement and make more ball control errors (Duncan, Fowler, George, Joyce, & Hankey, 2015). Running velocity has been shown to be slower (Smith, Marcora, & Coutts, 2015), and the distance covered is 15 percent less when fatigued (Marcora, 2014). For cyclists, fatigue results in slower finish times (Pires, Silva-Júnior, Brietzke, Franco-Alvarenga, 2018).

Sources of fatigue include poor sleep quality – as poor sleep quality persists a higher rate of fatigue is present (Scott, Arslanian-Engoren, & Engoren, 2014). In a literature review of sleep loss and fatigue, researchers concluded that sleep loss, in any degree, can increase the feeling of

fatigue and negatively affect cognitive ability and performance (Veasey, Rosen, Barzansky, Rosen, & Owens, 2002). When an individual is fatigued due to lack of sleep, performance variables decline (Duncan, et. Al, 2015; Marcora, 2014; Marcora, Staiano, & Manning, 2009; Pires et al., 2018; Smith, Marcora, & Coutts, 2015). With respect to sleep, some researchers have shown that just thinking you received poor sleep makes people feel worse and perceive heightened levels of fatigue (Buboltz, Brown, & Soper, 2001; Buboltz, Jenkins, Soper, Woller, Johnson, & Faes, 2009) showing that sleep likely effects perceptions of physiological states.

Sleep is an important factor to our daily functioning. A short sleep duration (or sleep deprivation) has been defined as less than 7 hours of sleep per night (Center for Disease Control (CDC), 2017). In the United States, depending on geographical location, it is estimated that between 28.5 to 44.1 percent of people sleep short durations per 24-hour period. College aged adults fall right into the national average of short sleep duration at about 32 percent.(CDC, 2017) A high percentage of students reported irregular sleep patterns or short sleep duration (>8 hrs) or poor sleep quality (Shahid, Shen, & Shapiro, 2009; Vargas, Flores, & Robles, 2014). Twenty-five percent of adults also report having insufficient sleep 15 out of every 30 days (Office of Disease Prevention and Health Promotion (ODPHP), 2018). Overall, there is a high percentage of people who are sleep deprived or receive an improper amount of sleep according to recommendations, which may put them at a higher risk for health problems.

Improper amounts of sleep and poor sleep can lead to many physical and mental health problems when compared to good quality sleep (Lund, Reider, Whiting, & Prichard, 2010; ODPHP, 2018). In terms of physical health, chronic health conditions have many factors that play into the total risk percentage with sleep being one of them. For example, the risks for heart attacks, coronary heart disease, strokes, asthma, COPD, cancer, arthritis, chronic kidney disease,

and diabetes are all higher in individuals that reported a shorter sleep duration (CDC, 2017). Sleep is also necessary to fight off infection and support metabolism (ODPHP, 2018). Too much sleep or not enough sleep also raises the risk for all-cause mortality (Cappuccio, Delia, Strazzullo, & Miller, 2010). Short duration sleepers (less than 5 hours of per 24-hour period) are at a 12 percent higher risk of all-cause mortality and longer duration sleepers (greater than 9 hours per 24-hour period) are 30 percent more likely to die from all-cause mortality

Sleep has also been linked to cognitive function and mental health. Sleep deprivation has been linked to daytime sleepiness and decreased mental sharpness; negatively affecting cognitive ability and performance (Irwin, 2015; Leonard, Fanning, Attwood & Buckley, 1988; Shahid, Shen, & Shapiro, 2009), which includes performing well in school and at work. When sleep deprivation occurs, the risk for developing new-onset depressive symptoms are higher (Lee, Park, Nam, & Park, 2016). Mood (anger, confusion, depression and tension), memory, and stress levels are also directly affected by sleep (Irwin, 2015; Lund, Reider, Whiting, & Prichard, 2010). As the amount of sleep declines, the amount of time it takes to make decisions also declines (Ratcliff & Dongen, 2009). The ability to stay on task and not let the mind wander is also adversely affected when the body is sleep deprived (Poh, Chong, & Chee, 2016). Poor sleep practices lead to decline in mental health and cognitive function although when sleep quality is improved defects associated with sleep quality are diminished (Selby, 2013).

Military Applications

In recent times, the military has looked to use applied sports psychology to help improve their soldiers. Improvements in confidence is one of the focuses the military has in its Army Center for Enhanced Performance (Hite, 2011; Meyer, 2018). The United States military thrives on their soldiers being apt and ready for battle. Officers and enlisted personal are asked to make

decisions daily that hang lives in the balance (Headquarters, Department of the Army, 2006; Useem, 2010).

A soldier needs quality sleep, exercise, and sustenance to be at peak performance (Headquarters, Department of the Army, 2006). Sleep has been noted as vital part of the Army Performance triad (Army Public Health Center, 2015). Researchers have shown that military personnel are at a higher risk for sleep disorders and sleep disorder prevalence has doubled and tripled in some cases (Caldwell, Knapik, & Lieberman, 2017). In one study, only 37 percent of U.S. military members slept the recommended 7-8 hours of sleep and over half reported poor sleep quality (Troxel et al., 2015). There are many reasons sleep is poor in the military; for example, physical and emotional stressors, poor sleep practices and environments (Caldwell, Knapik, & Lieberman, 2017). Poor sleep quality effects combat readiness/physical performance (Lentino, Purvis, Murphy, & Deuster, 2013), and over 50 percent of service members report being fatigued at least 1-2 times per week (Troxel et al., 2015).

The purpose of this study was to understand and observe the effect of sleep quality on self-efficacy and performance. The Army Physical Fitness Test (APFT) was used to assess muscular fitness and cardiovascular fitness. Standards are set for each test by age and gender and military members are assessed through the amount of repetitions and time on each individual test combined at the end to yield a total score. Failure of the APFT is associated with lower fitness level, premature discharge, and significant career disruption (U.S. Department of the Army, 2016). Failure of the APFT also have a cost to the individual soldier and the U.S Military. The military tests their member in order to gauge their physical readiness for battle.

Chapter II

Method

Participants

Participants were 84 cadets from an upper Midwest Army ROTC Program. They were full time college students balancing a school schedule along with early morning physical training and duties in the military science program. There were 30 females and 54 males. Ages ranged from 18 to 25 years with an average of 19.90 years ($SD = 1.62$). Military science cadet levels were 31 MS1s Freshman, 32 MS2 Sophomore, 16 MS3 Junior, and 5 MS4 Senior.

Measures

Pittsburgh Sleep Quality Index

The Pittsburgh Sleep Quality Index (PSQI: Buysse, Reynolds, Monk, Berman, & Kupfer, 1989; see Appendix A) was used to assess sleep quality. The index consists of 19 items that yielded scores on 7 subscales (sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleep medications, and daytime dysfunction). Each item was rated from 0 to 3. The subscale scores were used to compute a total score that ranges from 0 to 21; higher scores were indicative of poor sleep quality. Cronbach Alpha was reported between 0.69 and 0.83 depending on the population (De la Vega et al., 2015). The Alpha for this study was .75.

Epworth Sleepiness Scale

The severity of daytime sleepiness was evaluated using the Epworth Sleepiness Scale (Johns, 1991; see Appendix B). Cadets were asked to indicate if they would never doze (0), had a

slight chance of dozing (1), had a moderate chance of dozing (2), or had a high chance of dozing (3) in 8 common situations (e.g., studying, sitting in lecture, driving, etc.). Total scores on the scale can range from 0 to 24 where scores greater than 10 indicate abnormal daytime sleepiness and scores greater than 16 suggest pathological sleepiness. Cronbach's Alpha for this sample was .76.

Sleep Quantity Assessment

A sleep quantity assessment evaluated sleep debt using the Rosenkind formula (M. R. Rosenkind, personal communication, May 26, 2019; see Appendix C). Cadets were asked to report the amount of sleep obtained each night for 5 consecutive nights, starting from six days prior to the physical fitness test. The 5 consecutive nights included weekdays and weekends. The amount was totaled to determine the overall amount of sleep obtained within a 5-day period. In addition, cadets were asked to think about the number of hours of sleep obtained when they felt the most alert and performed their best in class and training. If this amount was unknown, they were instructed to report 8 hours. This amount was multiplied by 5 to determine the amount of sleep required in a 5-day period for optimal performance. The total amount of sleep obtained was then divided by the hours of sleep participants reported to be when they felt the most alert and performed to their best. The closer the percent to one reflected an optimal sleep quantity for the participant. Scores ranged .45 (45%) to 1.67 (167%). The acceptable threshold for this study was .90, meaning cadets with $> .90$ were only missing 10 percent of their sleep in the last five days; for a recommended 40 hours per 5-day period means they were lacking 4 hours of sleep.

Self-Confidence

The Competitive Trait Anxiety Inventory 2 (CTAI-2: Albrecht & Feltz, 1987; see Appendix D) is a 27-item assessment of self-confidence and anxiety. Only the confidence subscale was used (9 items). Cadets rated the intensity with which they usually experience each of the nine items before or during competition/performance on a 4-point Likert type scale ranging from 1 (*not at all*) to 4 (*very much so*). Sample items were the following: I feel at ease; I feel comfortable; I feel self-confident; I feel secure; I'm confident I can meet the challenge, etc. Scores can range from 9 to 36. Previous Alpha for this subscale was shown to be .83 (Neil, Mellalieu, & Hanton, 2006). Cronbach's Alpha for this sample was .93.

Self-efficacy

Self-efficacy was assessed using a task-specific measure assessing cadets' thoughts about their ability and score on an upcoming physical fitness test (see Appendix E). The self-efficacy questionnaire contained items regarding scores in each individual event (pushups, sit-ups and 2 mile run) along with a total score. Cadets were asked to indicate the strength of their belief to obtain certain scores (increasing in difficulty) using a 1 (*low degree of certainty*) to 10 (*high degree of certainty*). The self-efficacy measure was formatted in increments of 5 points, ranging from zero to 100 ("How confident are you that you will score a 50 on the Push-up portion of the APFT?" and then: "How confident are you that you will score a 55 on the Push-up portion of the APFT?"). The same 0 to 100 format (20 questions each) was used for sit-ups and the 2-mile run. The overall APFT score started at 50 points and increased by 10 points up to 300. For each measure, the total scores were computed by adding efficacy ratings together and then dividing by the number of questions in the subscale. Alphas for each measure were high, ranging from .95-.97.

Performance

The APFT is the Army's measurement of physical fitness. It measures a soldier's overall fitness through three parts of the test: sit-ups, push-ups, and the two-mile run. Raw scores were recorded on a scorecard then calculated into scaled scores. Scaled scores were calculated through the Army's standards (U.S. Department of the Army, 2010; see Appendix F); different scores are given by gender and age. The total scores range from 0 to 300, and each event from 0 to 100.

Procedure

Approval to conduct this study was provided by the Institutional Review Board (see Appendix G). Cadets were contacted via email and encouraged to participate by completing the surveys online (Qualtrics link). The survey collected the background information that was used to describe the participants (see Appendix H), and measures for PSQI, Sleep Quantity, self-confidence (CTAI subscale), and self-efficacy. The deadline to take the survey was 11:59pm the night before the cadets were scheduled to complete the Army's APFT. Three testing dates were used; so, the same person could have participated three times in this study ($n = 133$).

Chapter III

Results

Preliminary analysis were run for accuracy of data, missing values, and assumptions of multivariate factors. Two cases had filled out the self-efficacy for the push-up, sit-up, two-mile and overall APFT incorrectly and were subsequently deleted. SPSS Statistics 25 was used for data analysis. Descriptive statistics for each measure can be found in Table 1.

Table 1

Descriptive statistics

| | Min | Max | Mean | SD |
|----------------|-------|--------|--------|-------|
| Global PSQI | 0.00 | 17.00 | 8.20 | 3.46 |
| ESS | 0.00 | 18.00 | 7.59 | 3.91 |
| Sleep Quantity | 0.45 | 1.67 | 0.89 | 0.17 |
| CTAI2 | 9.00 | 36.00 | 23.44 | 6.66 |
| SE PU | 1.30 | 10.00 | 8.12 | 1.81 |
| SE SU | 2.05 | 10.00 | 8.37 | 1.71 |
| SE 2M | 1.00 | 10.00 | 8.13 | 1.97 |
| SE APFT | 1.15 | 10.00 | 8.12 | 1.95 |
| Pushup Score | 41.00 | 100.00 | 87.56 | 14.52 |
| Situp Score | 22.00 | 100.00 | 82.17 | 18.60 |
| 2Mile Score | 8.00 | 100.00 | 80.77 | 17.98 |
| APFT total | 80.00 | 300.00 | 250.47 | 43.08 |

Note. Global Pittsburgh Sleep Quality Index Score (Global PSQI); Epworth Sleepiness Scale (ESS); Rosenkind Formula (Sleep Quantity); Competitive Trait Anxiety Index – 2 (CTAI-2); Self-Efficacy Push-Up (SE PU); Self-Efficacy Sit-Up (SE SU); Self-Efficacy 2 Mile Run (SE 2M); Self-Efficacy Total APFT (SE APFT).

PSQI total scores ranged from 0 to 17 with a mean score of 8.20 ($SD = 3.46$). A score of >5 indicated those with greater sleep disturbances (approximately 24.8% of this sample). Sleep quantity scores ranged from 0.45 to 1.67 and 53.4% of the sample had a sleep quantity score $> .90$ showing that they did not have sleep debt (1.0) or had very little sleep debt (.90-1.0) in the 5 days leading up to the test. ESS scores ranged from 0 to 18, and 54.14% of the sample had a score of greater than 6 suggesting normal sleepiness, 23.3% had a score greater than 10

indicating abnormal sleepiness, and 1.5% had a score 16 and greater, suggesting pathological sleepiness.

According to responses on the CTAI-2, the mean was 23.44 indicating the sample was fairly confident. When analyzed by each question asked the average answer was 2.60 (out of 4) indicating that the average question was met with the answer “*moderately so.*” Self-efficacy measures also indicated that the sample was confident in their abilities – all self-efficacy mean scores were above 8 on the 10 point scale.

Performance measures means indicated that the sample scored on average about 80 points on each individual test. Scores >60 are required for a passing score; 2.3 percent failed the Push-up event, 12.0 percent failed the Sit-up event, 8.3 percent failed the 2-mile run event. The APFT cannot be passed without a score >60 in each event and a total score of 180, 16 percent did not either pass 1 event or scored below 180 on the APFT. Generally, failure of the APFT would result in a re-test, no retests were included in the data.

Before running the main analyses, ANOVAs were run to see if female cadets would have better sleep quality when compared to their male counter parts, and if there were gender differences in confidence and self-efficacy (Feltz, Short, & Sullivan, 2008). The descriptive statistics for each measure, and corresponding p value, according to gender are in Table 2. Only the Competitive Trait Anxiety Inventory-2 (CTAI-2) and Self-efficacy two-mile (SE 2M) were statistically significant (CTAI-2: $F(1, 131) = 16.40, p = .00$; SE 2M: $F(1, 131) = 16.20, p = 0.04$) with males scoring higher than females.

Table 2
Descriptive Statistics for Gender Differences

| | Male(n=89) | | | | Female(n=44) | | | | p | t |
|----------------|------------|-------|-------|--------|--------------|-------|--------|--------|-------------|-------|
| | Mean | SD | Min | Max | Mean | SD | Min | Max | | |
| Global PSQI | 8.04 | 3.41 | 0.00 | 17.00 | 8.50 | 3.57 | 2.00 | 16.00 | 0.48 | -0.71 |
| ESS | 7.17 | 3.96 | 0.00 | 18.00 | 8.43 | 3.72 | 0.00 | 18.00 | 0.08 | -1.77 |
| Sleep Quantity | 0.90 | 0.17 | 0.50 | 1.67 | 0.87 | 0.16 | 0.45 | 1.23 | 0.31 | 1.02 |
| CTAI2 | 25.00 | 6.53 | 9.00 | 36.00 | 20.30 | 5.81 | 9.00 | 33.00 | 0.00 | 4.05 |
| SE PU | 8.20 | 1.86 | 1.30 | 10.00 | 7.96 | 1.74 | 3.20 | 10.00 | 0.48 | 0.71 |
| SE SU | 8.48 | 1.85 | 2.05 | 10.00 | 8.14 | 1.38 | 3.55 | 10.00 | 0.28 | 1.09 |
| SE 2M | 8.38 | 1.86 | 1.45 | 10.00 | 7.64 | 2.10 | 1.00 | 10.00 | 0.04 | 2.07 |
| SE APFT | 8.25 | 1.98 | 1.73 | 10.00 | 7.85 | 1.87 | 1.15 | 10.00 | 0.26 | 1.13 |
| Pushup Score | 86.55 | 15.45 | 41.00 | 100.00 | 89.91 | 11.37 | 62.00 | 100.00 | 0.20 | -1.34 |
| Situp Score | 82.73 | 19.73 | 22.00 | 100.00 | 80.32 | 17.79 | 29.00 | 100.00 | 0.50 | 0.49 |
| 2Mile Score | 80.92 | 19.63 | 8.00 | 100.00 | 80.82 | 13.80 | 48.00 | 100.00 | 0.98 | 0.09 |
| APFT total | 250.20 | 46.58 | 80.00 | 300.00 | 250.93 | 35.63 | 159.00 | 300.00 | 0.93 | -0.18 |

Note. Global Pittsburgh Sleep Quality Index Score (Global PSQI); Epworth Sleepiness Scale (ESS); Rosenkind Formula (Sleep Quantity); Competitive Trait Anxiety Index – 2 (CTAI-2); Self-Efficacy Push-Up (SE PU); Self-Efficacy Sit-Up (SE SU); Self-Efficacy 2 Mile Run (SE 2M); Self-Efficacy Total APFT (SE APFT).

Correlations were computed among the variables (see Table 3). All sleep measures correlated with each other. The PSQI and ESS were positively correlated because in both measures higher numbers mean a worse sleep quality. Sleep duration was correlated negatively with both PSQI and ESS, in the sleep duration measure a higher number means that the participant is getting more sleep, so a negative correlation is fitting. The CTAI-2 and the scores from the self-efficacy measures were all positively correlated. The performance measures were all significantly correlated.

With respect to the correlations among sleep and confidence and self-efficacy scores, the PSQI was significantly negatively correlated with all scores except the SE 2M. These correlations show that participants who had poorer sleep quality also had lower self-efficacy. For the ESS, the only significant correlation was with the CTAI-2. A higher number on the ESS, like the PSQI indicates worse sleep quality, so this value and direction indicates that those with

increased fatigue were less confident. There were no significant correlations among sleep quantity and confidence and self-efficacy measures.

Table 3

** Correlation is significant at the 00.01 level (2-tailed). * Correlation is significant at the 00.05 level (2-tailed)

Note. Global Pittsburgh Sleep Quality Index Score (Global PSQI); Epworth Sleepiness Scale (ESS); Rosenkind Formula (Sleep Quantity); Competitive Trait Anxiety Index – 2 (CTAI-2); Self-Efficacy Push-Up (SE PU); Self-Efficacy Sit-Up (SE SU); Self-Efficacy 2 Mile Run (SE 2M); Self-Efficacy Total APFT (SE APFT).

Correlations between sleep and performance were statistically significant for the PSQI and Sit-up score, 2mile score, and APFT total, showing that poorer sleep was associated with poorer performance. The only other correlation that was statistically significant was between sleep quantity and push-up performance. The negative correlation shows that the more sleep a participant got, the less push-ups were performed on the push-up performance portion. Note that as PSQI and the ESS number's go up, the worse of an outcome it is.

All measures of confidence and self- efficacy were significantly correlated with all of the performance measures. As expected, in terms of measurement, the correlations between each self-efficacy and performance “pair” were the highest. The correlations show the positive relationships between self-efficacy and performance (the cadets who were more confident were also more likely to score higher on their performance measure).

If self-efficacy/confidence and sleep are related to performance, then a combination of the scores from these measures should predict a significant proportion of variance in performance scores (as based on the correlations). To maximize the prediction of performance, a

hierarchical multiple regression was used. From a theoretical perspective, self-efficacy/confidence should be the strongest predictors of performance, so they were entered first (block 1). All sleep measures were entered together next (block 2). The rationale for this order of entry was based on self-efficacy theory. Self-efficacy should predict performance, and sleep, as a physiological state, is a source of self-efficacy. These regressions were run separately for push-ups, sit-ups, mile run and total performance.

For push-ups, the 5 variables (PSQI, Sleep Quantity, ESS, CTAI-2, SE) predicted a significant proportion of variance in performance (64%, Adjusted $R^2 = .39$), $F(5, 127) = 17.64$, $p = .00$). Examination of the unique contribution of the variables to the total variance accounted for by the model indicated that self-efficacy, the CTAI-2, and sleep duration were significant predictors (see Table 4). Self-efficacy was a positive predictor (more confidence, the better you do); but sleep quantity was negative (too much sleep, the worse a person performed).

For sit-ups, the 5 variables (PSQI, SD, ESS, CTAI-2, SE) predicted a significant proportion of variance in performance (72%, Adjusted $R^2 = .49$), $F(5, 127) = 26.63$, $p = .00$). Examination of the unique contribution of the variables to the total variance accounted for by the model indicated that the only significant predictors were self-efficacy and the CTAI-2 (more confidence, the better you do).

For the 2 mile run, the 5 variables (PSQI, SD, ESS, CTAI-2, SE) predicted a significant proportion of variance in performance (67%, Adjusted $R^2 = .42$), $F(5, 127) = 20.31$, $p = .00$). Examination of the unique contribution of the variables to the total variance accounted for by the model indicated that self-efficacy was a significant predictor, and so was PSQI and sleep duration. Self-efficacy was a positive predictor (more confidence, the better you do); but the

PSQI and sleep quantity were negative (too much sleep/or poor sleep quality effected performance negatively).

| Sleep Quantity | | | | -0.16 | -2.35 | 0.02* |

* regression is significant

Note. Global Pittsburgh Sleep Quality Index Score (Global PSQI); Epworth Sleepiness Scale (ESS); Rosenkind Formula (Sleep Quantity); Competitive Trait Anxiety Index – 2 (CTAI-2); Self-Efficacy Push-Up (SE PU); Self-Efficacy Sit-Up (SE SU); Self-Efficacy 2 Mile Run (SE 2M); Self-Efficacy Total APFT (SE APFT).

For total performance, the 5 variables (PSQI, SD, ESS, CTAI-2, SE) predicted a significant proportion of variance in performance (70%, Adjusted $R^2 = .47$), $F(5, 127) = 24.00$, $p = .00$). Examination of the unique contribution of the variables to the total variance accounted for by the model indicated that self-efficacy was a significant predictor, and so was PSQI and sleep quantity.

Chapter IV

Discussion

To answer the research question of: Are cadets who have poorer sleep quality less efficacious in their abilities and score lower on their APFT; correlations and regressions were primarily used in the analyses. The results of the study showed the self-efficacy had a positive and significant effect on the performance of the cadets taking the APFT. Researchers have explored the links between sleep and performance in athletes (e.g., Halson & Juliff, 2017), but few have explored the same research in a military setting. Wagstaff (2015) is one exception who has drawn similarities between athletes and military members.

The results were consistent with many of the findings by other researchers. The fatigue rates of the participants were 23.3% (ESS scores). This number is well below the findings of authors such as Aliyu (2007) who stated that 37.9 of their population was fatigued, and above Aritake et. Al. (2014) which stated their population had a fatigue prevalence of 17.2. It is also noted that as poor sleep quality persists, a higher rate of fatigue is present. In this study, participants scored greater than 5 on the PSQI 24.8% of the time suggesting higher disturbances of sleep also demonstrating the previously published sleep trends.

According to Bandura (1997), the impact of physiological states on efficacy beliefs will depend on things such as situational factors and the meaning given to them. Most participants in

the sample were confident, if not very confident. It's due noting the need to perform on the APFT may have affected the confidence level of the participants. If a participant failed any test it effected their grade, added extra training and the participant had to retake the test again. Generally, participants are tested three times a semester: once at the beginning, middle, and end, with the expectation of improvement each time. Researchers have shown that if a person is more confident, than they will perform better on the subsequent test (Hays, Thomas, Maynard, & Bawden, 2009).

There were no significant differences between men and women in this study with the exception of two confidence measures. In this study, men demonstrated higher confidence compared to women on the 2 mile run (SE 2M) and the CTAI-2. These results show that males tend to be more confident when asked about the tasks they are perform under the same pressures that females face. When comparing sleep scores from each measure on average, women's sleep scores were on average (comparing means) worse than their male counter parts, but the ANOVA was insignificant for each measure. Due to the ANOVAs being insignificant analysis continued without comparing gender.

The relationships among each variables through correlations exemplified normal expectations, confidence and self-efficacy variables were positively correlated and so were the correlations between each self-efficacy measure and its subsequent performance measure. The CTAI-2 was also positively correlated with all performance outcomes demonstrating that all measures were effective tools for measuring the efficacy the participants had with regards to the upcoming APFT. The correlation analyses revealed a trend that those with lower sleep quality (scoring higher on the Global PSQI, and ESS) had lower self-efficacy, although the population demonstrated overall confidence. When analyzing the correlations between Sleep Quantity and

the confidence measures, only Pushup score was significant, but all performance measures were negatively correlated. The negative correlations between Sleep Quantity and performance measures demonstrated if participants slept more than the time they felt the most rested than their performance scores suffered; this result is an example of how too much sleep can effect performance. Sleeping too much or too little effected performance negatively. When participants got the amount of sleep they felt was effective for them, they performance better.

The multiple regression analysis showed that the self-efficacy measures were the most useful in predicting the subsequent performance outcome. The second step, that included all sleep measures, showed that for three of the four performance outcomes, the global PSQI was a significant predictor followed by sleep quantity. Beta weights from each step raise a question about the potential mediating effect of self-efficacy on sleep and performance. Overall, although sleep and self-efficacy were significant predictors of performance, they accounted for only a small proportion of variance.

In conclusion, sleep is important and an integral part of life, especially in the military. The participants in this study were cadets on their way to becoming Army officers and commanding troops. The value of sleep and sleep quality is usually an overlooked part of everyday life. How we sleep can affect our confidence toward a given task and effect our output when it comes to said performance or physical tests. Further implications of this study may include a bigger emphasis on sleep education for military students that they can pass down to their subordinates.

Future researchers should address the more complicated pathways that connect these variables. They may also consider using more accurate ways to measure sleep; for example, wearable technology like FitBit. Different performance measures could also be used. The Army

has a new physical fitness test that includes more events and shorter break times. Limitations of this study include the sleep measures, small sample size, and lack of independence in the data (the survey used in this study was taken multiple times by some individuals but at different points in time ranging two to three months apart). When measuring sleep, the most effective way is in a lab as self-reports may be inaccurate, and participants tend to overestimate their quality of sleep. Due to the data being only collected in one location the sample size was small, and the sample's scores did not have a lot of variance so collecting data at different locations and maybe under different conditions (field tests during boot camp) may be more helpful. However, this study was the first of its kind exploring sleep and self-efficacy and performance.

Appendix A

Questions About Your Sleep

The following questions relate to your usual sleep habits during the **PAST Month** only. Your answers should indicate the most accurate reply for the majority of days and nights in the past week.

During the PAST MONTH, what time have you usually gone to bed at night?

Bed time:

Hour

Minute

AM/PM

During the PAST MONTH, how long has it usually taken you to fall asleep each night?

Hours

Minutes

During the PAST MONTH, what time have you usually gotten up in the morning?

Getting up time:

Hour

Minute

AM/PM

During the PAST Month, how many hours of actual sleep did you usually get at night?

(This may be different than the number of hours you spent in bed.)

Hours of sleep per night:

Hours

Minutes

During the PAST MONTH, How many hours were you in bed

Hours spent in Bed:

Hours

Minutes

During the PAST MONTH, how often have you had trouble sleeping because you...

| | Not During the past Month (0) | Less than once a week (1) | Once or Twice a Week (2) | Three or more times a week |
|---|-------------------------------|---------------------------|--------------------------|----------------------------|
| Cannot get to sleep within 30 minutes | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Wake up in the middle of the night or early morning | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Have to get up to use the bathroom | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Cannot breathe comfortably | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Cough or snore loudly | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Feel too cold | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Feel too hot | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Have bad dreams | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Have pain | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Other reason (s), please describe, including how often you have had trouble sleeping because of this reason (s): <input type="text"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |

| | Not During the past Month (0) | Less than once a week (1) | Once or Twice a Week (2) | Three or more times a week |
|---|-------------------------------|---------------------------|--------------------------|----------------------------|
| During the past month, how often have you taken medicine (prescribed or "over the counter") to help you sleep? | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| During the past month, how often have you had trouble staying awake while driving, eating meals, or engaging in social activity | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| During the past month, how much of a problem has it been for you to keep up enthusiasm to get things done? | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |

During the PAST MONTH, how would you rate your sleep quality overall?

- Very Good
 Fairly Good
 Fairly Bad
 Very Bad

Appendix B

How likely are you to doze off or fall asleep in the following situations, in contrast to feeling just tired?
 This refers to your usual way of life in recent times. Even if you have not done some of these things recently try to work out how they would have affected you. Use the following scale to choose the most appropriate number for each situation:

| | No chance of dozing | Slight chance of dozing | Moderate chance of dozing | High chance of dozing |
|---|-----------------------|-------------------------|---------------------------|-----------------------|
| Sitting and reading | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Watching TV | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Sitting inactive in a public place (e.g. a theater or a meeting) | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| As a passenger in a car for an hour without a break | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Lying down to rest in the afternoon when circumstances permit (not napping) | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Sitting and talking to someone | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| Sitting quietly after a lunch without alcohol | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| In a car, while stopped for a few minutes in traffic | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |

Appendix C

Report the amount of sleep obtained each night for the last 5 consecutive nights

| Thursday, June 20th | Friday, June 21st | Saturday, June 22nd | Sunday, June 23rd | Monday, June 24th |
|----------------------|----------------------|----------------------|----------------------|----------------------|
| <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> | <input type="text"/> |

For the next question please indicate the number of hours of sleep obtained when you have felt the most alert and performed your best.
If this amount is unknown, report 8 hours.

Appendix D

The following are several statements that you can use to describe your feelings before The APFT. **Read** each statement and mark the appropriate box to indicate how you feel right now, **at this moment**. There are no right or wrong answers.

Do not spend too much time on any one statement

| | Not at all | Somewhat | Moderately so | Very much so |
|---|-----------------------|-----------------------|-----------------------|-----------------------|
| I feel at ease. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I feel comfortable. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I feel self-confident. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I feel secure. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I'm confident I can meet the challenge. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I'm confident about the APFT | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I feel mentally relaxed. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I'm confident because I mentally picture myself reaching my goal. | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I'm confident of coming through under pressure | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |

How sure you are in Achieving the score on the Sit-up portion of the APFT in the condition you currently are in?

1= small degree of certainty 10= High degree of certainty

| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|-----------------------|
| I am certain I will achieve 5 points on the Sit-up portion of the APFT | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I am certain I will achieve 10 points on the Sit-up portion of the APFT | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |
| I am certain I will achieve 15 points on the Sit-up portion of the APFT | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> | <input type="radio"/> |

Scoring standards are used to convert raw scores to point scores after test events are completed. Male point scores are indicated by the M at the top and bottom of the shaded column. Female point scores are indicated by the F at the top and bottom of the unshaded column. To convert raw scores to point scores, find the number of repetitions performed in the left-hand column. Next, move right along that row and locate the intersection of the soldiers appropriate age column. Record that number in the Push-Up points block on the front of the scorecard.

Scoring standards are used to convert raw scores to point scores after test events are completed. To convert raw scores to point scores, find the number of repetitions performed in the left-hand column. Next, move right along that row and locate the intersection of the soldier's appropriate age column. Record that number in the Sit-Up points block on the front of the scorecard.

2-MILE RUN STANDARDS

| Principal Investigator(s): | Andrew Lautner |
| Project Title: | Relations Among Sleep Quality, Self Efficacy and Performance in a Military Setting |
| IRB Project Number: | IRB-201811-113 |
| Project Review Level: | Exempt 2 |
| Date of IRB Approval: | 11/26/2018 |
| Expiration Date of This Approval: | 11/25/2021 |

The application form and all included documentation for the above-referenced project have been reviewed and approved via the procedures of the University of North Dakota Institutional Review Board.

If you need to make changes to your research, you must submit a Protocol Change Request Form to the IRB for approval. No changes to approved research may take place without prior IRB approval.

This project has been approved for 3 years, as permitted by UND IRB policies for exempt research. You have approval for this project through the above-listed expiration date. When this research is completed, please submit a Termination Form to the IRB.

Appendix H

Demographics

What is your gender?

- Male
- Female

What is your age in years?

what is your MS level?

- MS1
- MS2
- MS3
- MS4
- MS5

Name

- (This will only be used to retrieve your APFT score)
