ABSTRACT

Objectives: Chronic obstructive pulmonary disease (COPD) is becoming a leading cause of morbidity and mortality in China. In the IMPACT trial, fluticasone furoate[FF]/umeclidinium[UMEC]/vilanterol[VI] single-inhaler triple therapy demonstrated lower rates of moderate/severe exacerbations than dual therapy with FF/VI or UMEC/VI in patients with symptomatic COPD and a history of exacerbations. This analysis investigates the China cohort and its consistency with the overall ITT population.

Methods: 10,355 patients were randomized 2:2:1 to once-daily FF/UMEC/VI 100/62.5/25 µg, FF/VI 100/25 µg, or UMEC/VI 62.5/25 µg for 52 weeks. Endpoints included: annual rates of exacerbations, time-to-first on-treatment moderate/severe exacerbation and change from baseline in trough forced expiratory volume in 1 s (FEV₁) at Week-52. Clinical trial registration is NCT02164513 (CTT116855).

Results: 535 patients (5.2%) were from China. Annual on-treatment moderate/severe exacerbation rate was 0.81 with FF/UMEC/VI versus 0.96 with FF/VI (rate ratio: 0.84; 95% confidence interval [CI]: 0.64, 1.11; *p* = .227) and 0.80 with UMEC/VI (rate ratio: 1.02; 95% CI: 0.72, 1.44; *p* = .929). Hazard ratio for time-to-first moderate/severe exacerbation was 0.84 (95% CI: 0.63, 1.11; *p* = .218) for FF/UMEC/VI versus FF/VI and 0.89 (95% CI: 0.62, 1.27; *p* = .516) versus UMEC/VI. Significant improvements in mean change from baseline in trough FEV₁ were observed for FF/UMEC/VI versus FF/VI (treatment difference 137 mL; 95% CI: 86, 188; *p* < .001) and UMEC/VI (63 mL; 0, 125; *p* = .050). Health status was improved with FF/UMEC/VI versus both dual therapies. Results were similar to the overall ITT population. No new safety signals were identified.

Conclusions: Single-inhaler triple therapy with FF/UMEC/VI versus FF/VI or UMEC/VI reduced the rate and risk of exacerbations, and improved lung function and health status in the China cohort similar to the overall ITT population. No new safety signals were identified.

Introduction

Chronic obstructive pulmonary disease (COPD) is a progressive respiratory disease characterized by persistent respiratory symptoms, including dyspnea, cough and/or sputum production, as well as airflow limitation, which results in a decrease in lung function¹. The global burden of COPD is high, with the World Health Organization listing the disease as the third leading cause of death worldwide in 2016². Furthermore, this substantial burden is predicted to continue with COPD projected to remain a leading cause of death by 2030³.

The burden of COPD in China is greater than that seen in developed countries, with the condition rapidly becoming a

leading cause of morbidity and mortality among Chinese people^{4,5}. The prevalence of COPD in China has recently been estimated to be between 8.6% and 13.6%, with a higher prevalence in men than in women^{4,6}. Findings from the Global Burden of Disease Study 2010 show that, regardless of gender, China has higher mean years of life lost to COPD when compared with all other G20 members apart from India⁷. It has also been noted that approximately 70% of all COPD deaths worldwide occur in South and South East Asia^{5,8}. In a recent cross-sectional survey of a nationally representative sample of patients with COPD from China, the majority (56.4%) had mild disease (Global initiative for chronic Obstructive Lung Disease [GOLD] stage I), 36.3%

moderate disease (GOLD stage II), 6.5% severe disease (GOLD stage III), and 0.9% very severe disease (GOLD stage IV)⁶. Chinese physicians are encouraged to follow COPD therapy strategies recommended in the GOLD report, i.e. treatment escalation based on symptoms and exacerbation risk⁹. However, many physicians fail to implement these guidelines adequately and, as a result, appropriate use of COPD medication is inconsistent^{5,9}.

The GOLD management strategy for COPD recommends triple therapy with an inhaled corticosteroid (ICS), a long-acting muscarinic antagonist (LAMA), and a long-acting β_2 -agonist (LABA) in patients with persistent breathlessness or exercise limitation on dual ICS/LABA therapy, or in patients with recurrent exacerbations despite treatment with dual ICS/LABA or LAMA/LABA¹. The InforMing the PATHway of COPD Treatment (IMPACT) trial, conducted in 37 countries worldwide, compared once-daily single inhaler triple therapy (fluticasone furoate [FF]/umeclidinium [UMEC]/vilanterol [VI]) with two dual therapies (UMEC/VI [LAMA/LABA] and FF/VI [ICS/LABA]) in patients with symptomatic COPD with at least one moderate/severe exacerbation in the previous year. FF/UMEC/VI significantly reduced the rate of moderate/severe COPD exacerbations and improved lung function and health status compared with either dual therapy¹⁰.

The pharmacokinetic profile of inhaled COPD therapies can be impacted by a number of factors including lung receptor occupancy and the amount of drug absorbed into the systemic circulation, which could elicit additional pharmacological effects and contribute to the safety and tolerability profile of the drug¹¹. Moreover, responses to certain treatments have been reported to differ in Chinese patients compared to their Caucasian counterparts, thought to be caused in some cases by differences in the frequency of receptor polymorphisms in patients of differing ethnicity and in some cases to differing adherence to treatment^{12,13}. Differences in the pharmacokinetic profile of inhaled FF have been observed between Chinese and Caucasian populations, for example, higher FF plasma concentrations and higher C_{max} and area under the concentration–time curve (AUC) values, therefore it is of interest to evaluate the efficacy and safety of FF/UMEC/VI triple therapy in patients with COPD in China¹⁴. The IMPACT trial was conducted in 37 countries and analyses by geographic region were performed to investigate potential differences from the overall intent-to-treat (ITT) population in the efficacy and safety of FF/UMEC/VI triple therapy. In the analysis of IMPACT, patients enrolled in Japan, improvements in moderate/severe exacerbation rates, lung function and health status with FF/UMEC/VI versus FF/VI and UMEC/VI were similar as those seen in the overall ITT population, with no new safety signals identified¹⁵. Here we present results of a subgroup analysis based on patients from China enrolled in the IMPACT trial. The primary objective was to evaluate the efficacy of FF/UMEC/VI to reduce the annual rate of moderate/severe exacerbations compared with FF/VI or UMEC/VI dual therapy in the China cohort. Secondary objectives included evaluation of the long-term safety and other efficacy assessments of FF/UMEC/VI compared with dual therapies in this population. The purpose of

this analysis was to determine if the efficacy and safety data for patients from China enrolled in the IMPACT trial was consistent with the overall ITT population of the IMPACT trial.

Methods

Study design

The IMPACT trial (GSK study CTT116855, NCT02164513) is a Phase III, randomized, double-blind, parallel-group, multicenter trial conducted in 37 countries between June 2014 and July 2017. Here we report a subgroup analysis in patients from China. The trial design has been described in detail previously^{10,16}. Briefly, the total trial duration was approximately 55 weeks, consisting of a 2-week run-in period, a 52-week treatment period, and a 1-week safety follow-up period. All patients in the overall ITT population provided written informed consent. The trial was conducted in accordance with Good Clinical Practice guidelines and the provisions of the Declaration of Helsinki and received approval from local institutional review boards or independent ethics committees.

Study population

Eligibility criteria for enrollment in the trial have been reported previously¹⁰. Eligible patients were ≥ 40 years of age with a diagnosis of COPD as defined by the American Thoracic Society/European Respiratory Society (ATS/ERS)¹⁷, current or former smokers with a smoking history of ≥ 10 pack-years, had a COPD Assessment Test (CAT) score ≥ 10 at screening, and had either a post-bronchodilator forced expiratory volume in 1 s (FEV₁) $< 50\%$ of the predicted normal value and a history of ≥ 1 moderate or severe exacerbation in the previous year, or a post-bronchodilator FEV₁ of 50–80% of the predicted normal value and ≥ 2 moderate exacerbations or ≥ 1 severe exacerbation in the previous year. Patients had to have been receiving daily maintenance treatment for COPD for ≥ 3 months prior to screening.

Exclusion criteria have also been reported previously¹⁰. Of note, patients with pneumonia or a severe COPD exacerbation that had not resolved ≤ 14 days prior to screening and ≤ 30 days following the last dose of corticosteroids (if applicable) were excluded, as were those with respiratory tract infection (RTI) that had not resolved within 7 days of screening, abnormal chest X-ray or resting oxygen requirement of > 3 L/min at screening. Patients with a current diagnosis of asthma were also excluded.

The population comprised all randomized patients, excluding those who were randomized in error. The China cohort was derived from the overall IMPACT trial ITT population and only included patients enrolled in China across 41 sites.

Study treatments

Patients were randomized (2:2:1) to receive either once-daily triple therapy FF/UMEC/VI 100/62.5/25 μg , or dual therapy

FF/VI 100/25 µg, or UMEC/VI 62.5/25 µg administered *via* the Ellipta inhaler. Patients continued to use their existing COPD medications during the run-in period and were provided with salbutamol on an as-needed basis (rescue medication) throughout the trial.

Study endpoints

The trial endpoints have been described previously^{10,16}. This subgroup analysis evaluated the following endpoints in the China cohort: annual rate of on-treatment moderate/severe exacerbations (primary endpoint), and secondary efficacy endpoints of time-to-first on-treatment moderate/severe exacerbation, on-treatment severe exacerbations, and change from baseline in trough FEV₁ and change from baseline in St George's Respiratory Questionnaire (SGRQ) at Week 52. Other efficacy endpoints included the proportion of SGRQ responders (patients with ≥4-point decrease in SGRQ total score from baseline), change from baseline in CAT score, the proportion of CAT score responders (patients with ≥2-point decrease in CAT score from baseline), and rates of other exacerbations (mild/moderate/severe, moderate only, and requiring treatment with systemic/oral corticosteroids or antibiotics).

Mild exacerbations were defined as exacerbations that were self-managed by the patient and did not require treatment with oral/systemic corticosteroids or antibiotics, moderate exacerbations were defined as requiring treatment with oral/systemic corticosteroids and/or antibiotics, and severe exacerbations were defined as requiring hospitalization or resulting in death.

Safety endpoints included the incidence of adverse events (AEs), serious AEs (SAEs), and AEs of special interest (AESIs). AESIs are AEs that were prespecified AEs associated with the known profiles of ICS, LAMAs or LABAs and allow for a comprehensive review of safety data that is not limited to a specific Preferred Term. Adjudication of SAEs was performed by an independent adjudication committee, who categorized the primary event in the SAE report.

Statistical analyses

Details of sample size calculations have been described previously¹⁰. The trial was not powered for subgroup analysis by country. All summaries, analyses or comparisons performed for the China cohort are for descriptive purposes only. No multiplicity adjustment was applied for analyses of these data.

In the overall ITT population, the number of moderate or severe COPD exacerbations was analyzed using a generalized linear model assuming a negative binomial distribution with covariates of treatment group, sex, exacerbation history (≤1, ≥2 moderate/severe), smoking status (screening), geographical region, and post-bronchodilator % predicted FEV₁ (screening)¹⁰. In the China cohort, the region covariate was defined as China/Not China and an additional covariate of treatment group by region (China/Not China) interaction was also included in the analysis. Time-to-first

on-treatment moderate or severe COPD exacerbation was analyzed using Cox proportional hazards model. Least squares (LS) mean change from baseline in trough FEV₁ was analyzed using a mixed-model repeated measures (MMRM) analysis. For the overall ITT population, covariates for FEV₁ included group, smoking status (screening), geographical region, visit, baseline, baseline-by-visit, and treatment group-by-visit interactions¹⁰. For the China cohort, the analyses included the same covariates, except for geographical region which was replaced with China/Not China, and the addition of treatment group by region, visit by region and treatment group by a visit by region interactions. For the overall ITT population, the proportion of SGRQ and CAT responders was analyzed using a generalized linear mixed model with a logit link function with the following covariates: treatment group, smoking status (screening), geographic region, visit, baseline value, and baseline-by-visit and treatment-by-visit interactions¹⁰. For the China cohort, the analyses included the same covariates in the model as the overall ITT population, except for geographic region which was replaced with China/Not China. The proportion of patients reporting AEs and SAEs was summarized for each treatment group. In the overall ITT population, multiplicity across selected treatment comparisons and key secondary endpoints was controlled using a hierarchical, truncated Hochberg closed testing procedure. Since all treatment comparisons in the testing hierarchy demonstrated adjusted *p*-values of <.001, both adjusted and unadjusted *p*-values were the same, and therefore only unadjusted *p*-values are presented here.

Results

Study population

Results in the overall ITT population have been previously published¹⁰. A total of 10,355 patients were randomized to treatment in the overall ITT population¹⁰. Of these, 535 were randomized in China (213 to FF/UMEC/VI, 216 to FF/VI, and 106 to UMEC/VI). Patient disposition for each study cohort is shown in [Supplementary Figure 1](#). The percentages of pre-screen or screen failures and reasons for failures were similar across cohorts. The majority of patients completed study treatment and completed the study; of those treated in the China cohort, 463 (87%) completed study treatment and 479 (90%) completed the study (patients who prematurely discontinued study treatment were encouraged to stay in the study to minimize data loss).

Demographics and baseline characteristics were similar across treatment groups. As anticipated, some demographic characteristics in the China cohort differed from the overall ITT population ([Table 1](#)). These included body mass index (BMI), % predicted post-bronchodilator FEV₁, CAT score and the proportion of current smokers, which were notably lower in patients from China compared with the overall ITT population. In the China cohort, the majority of patients were male (95–96% compared with 66–67% in the overall ITT), with mean age ranging from 65.5 to 66.1 years across the

^cExacerbations in previous year.

^dOverall ITT: N = 4142, 4124, and 2061 for FF/UMEC/VI, FF/VI, and UMEC/VI, respectively.

^eFormer smokers were defined as patients who had not smoked for >6 months prior to the visit.

Abbreviations: BMI, body mass index; CAT, COPD Assessment Test; COPD, chronic obstructive pulmonary disease; FEV₁, forced expiratory volume in 1 s; FF, fluticasone furoate; ICS, inhaled corticosteroids; ITT, intent-to-treat; LABA, long-acting β₂-agonist; LAMA, long-acting muscarinic antagonist; SD, standard deviation; UMEC, umeclidinium; VI, vilanterol.

treatment groups (compared with 65.2–65.3 in the overall ITT) and mean BMI ranging from 22.1 to 22.6 kg/m² (compared with 26.6 to 26.7 kg/m² in the overall ITT).

Primary efficacy analysis

In the China cohort, the rate of on-treatment moderate/severe exacerbations among patients randomized to FF/UMEC/VI was 0.81 per year, compared with 0.96 per year among those randomized to FF/VI (rate ratio: 0.84; 95% confidence interval [CI]: 0.64, 1.11; $p = .227$) and 0.80 per year among those randomized to UMEC/VI (rate ratio: 1.02; 95% CI: 0.72, 1.44; $p = .929$) (Table 2). These results were similar to the overall ITT population, with a point estimate in favor of FF/UMEC/VI versus FF/VI for the reduction in the rate of moderate/severe exacerbations. However, unlike in the overall ITT population, there was no difference between FF/UMEC/VI and UMEC/VI for this endpoint (Table 2).

Secondary efficacy analyses

In the analysis of the time-to-first moderate/severe exacerbation in the China cohort, hazard ratios for FF/UMEC/VI versus FF/VI and UMEC/VI were 0.84 (95% CI: 0.63, 1.11; $p = .218$) and 0.89 (95% CI: 0.62, 1.27; $p = .516$), respectively (Figure 1 and Table 2).

The proportion of patients experiencing severe exacerbations while on treatment in China were slightly higher compared to the incidence in the overall ITT population across FF/UMEC/VI, FF/VI, and UMEC/VI treatment groups (18% vs 11%, 17% vs 11%, and 17% vs 13%, respectively; Supplementary Table 1).

In the China cohort, FF/UMEC/VI significantly improved trough FEV₁ at Week 52 versus FF/VI (treatment difference 137 mL; 95% CI: 86, 188; $p < .001$) and versus UMEC/VI (treatment difference 63 mL; 95% CI: 0, 125; $p = .050$) (Figure 2). These improvements were similar to the overall population, although the point estimates for the between-treatment difference were in each case slightly higher in China than in the overall ITT (Figure 2).

Other efficacy endpoints

In the China cohort, there was a trend for an increased proportion of SGRQ total score responders at Week 52 with FF/UMEC/VI (49%) compared with FF/VI (41%; odds ratio [OR]: 1.40; 95% CI: 0.95, 2.05; $p = .090$) and UMEC/VI (41%; OR: 1.34; 95% CI: 0.83, 2.15; $p = .233$) (Figure 3). These differences were in line with those observed in the overall ITT population. At Week 52, the LS mean change from baseline data were consistent with the responder data, with significantly greater improvements seen with FF/UMEC/VI versus both dual therapy comparators (Supplementary Figure 2).

In the China cohort, the proportion of CAT score responders at Week 52 was higher in the FF/UMEC/VI group (41%) than in the FF/VI group (34%; OR: 1.31; 95% CI: 0.88, 1.96; $p = .180$); the proportion of CAT score responders at Week 52 was similar between FF/UMEC/VI and UMEC/VI (42%; OR:

0.90; 95% CI: 0.56, 1.46; $p = .665$) (Figure 4). At Week 52, there was no statistically significant difference in LS mean change from baseline in CAT score between treatment arms (Supplementary Figure 3).

In the China cohort, the rates of mild/moderate/severe COPD exacerbations and COPD exacerbations requiring systemic/oral corticosteroids were lowest in the FF/UMEC/VI group, compared with the FF/VI and UMEC/VI groups, which was also similar to what was observed in the overall ITT (Supplementary Table 2).

Safety endpoints

The incidence of AEs within the China cohort was similar across the three treatment groups, ranging from 75% to 79% (Table 3). The most common AESI in the China cohort were cardiovascular effects (15%) and pneumonia (4–13%). These were also among the most frequent AESI in the overall ITT population (10–11% and 5–8%, respectively). There was a higher incidence of pneumonia AESIs in the FF/UMEC/VI and FF/VI groups in the China cohort (13%) compared with the

Figure 2. Change from baseline in trough FEV₁. Abbreviations. CI, confidence interval; FEV₁, forced expiration volume in 1 second; FF, fluticasone furoate; ITT, intent-to-treat; LS, least squares; UMEC, umeclidinium; VI, vilanterol.

overall ITT population (8% and 7%), while the incidence of pneumonia adjudicated SAEs in the FF/UMEC/VI group was similar in China and the overall ITT (4% and 5%, respectively). There were no differences across the cohorts for the incidence of adjudicated pneumonia SAEs. The incidence of COPD exacerbation

with evidence of pneumonia adjudicated SAEs in the FF/UMEC/VI, FF/VI, and UMEC/VI groups was 6%, 5%, and 5% in China and 3%, 3%, and 3% in the overall ITT, respectively. The incidence of pneumonia/RTI without COPD exacerbation adjudicated SAEs in the FF/UMEC/VI, FF/VI, and UMEC/VI

Figure 3. Odds of SGRQ response with FF/UMEC/VI versus dual therapy comparators at Week 52. Response is defined as a decrease from baseline in SGRQ total score of ≥ 4 units. Non-response is defined as a decrease from baseline in SGRQ total score < 4 units below baseline, or an increase from baseline in SGRQ total score or a missing SGRQ total score with no subsequent on-treatment scores. Patients did not have a responder status derived if baseline SGRQ total score was missing, or if the SGRQ total score at a particular visit was missing but subsequent on-treatment SGRQ total scores were present. Abbreviations. n, number of responders; N, total number of analyzable patients; CI, confidence interval; FF, fluticasone furoate; ITT, intent-to-treat; SGRQ, St George's Respiratory Questionnaire; UMEC, umeclidinium; VI, vilanterol.

Figure 4. Odds of CAT response with FF/UMEC/VI versus dual therapy comparators at Week 52. Response is defined as a decrease from baseline in CAT score of ≥ 2 units. Non-response is defined as a decrease from baseline in CAT score < 2 units, or an increase from baseline in CAT score, or a missing CAT score with no subsequent non-missing on-treatment scores. Patients did not have a responder status derived if baseline CAT score was missing but subsequent on-treatment CAT scores were present. Abbreviations. CAT; COPD Assessment Test; n, number of responders; N, total number of analyzable patients; CI, confidence interval; FF, fluticasone furoate; ITT, intent-to-treat; UMEC, umeclidinium; VI, vilanterol.

groups was 2%, $< 1\%$, and 0% in China and 2%, 2%, and 1% in the overall ITT, respectively (Table 3).

SAEs occurred in 25–29% of patients in the China cohort, compared with 21–23% in the overall ITT population. In total, there were seven fatal SAEs in the China cohort (two [$< 1\%$] in the FF/UMEC/VI group, three [1%] in the FF/VI group, and two [2%] in the UMEC/VI group); these proportions were

similar to those seen in the overall ITT population (2% across treatment groups) (Table 3).

Discussion

In the China cohort of the IMPACT trial once-daily single-inhaler triple therapy with FF/UMEC/VI reduced the rate of

^aAESI were AEs which have specified areas of interest for ICS, LAMA, or LABA, or for patients with COPD.

Abbreviations. AE, adverse event; AESI, AE of special interest; COPD, chronic obstructive pulmonary disease; CV, cardiovascular; FF, fluticasone furoate; GI, gastrointestinal; ICS, inhaled corticosteroids; ITT, intent-to-treat; LABA, long-acting β_2 -agonists; LAMA, long-acting muscarinic antagonists; LRTI, lower respiratory tract infection; MedDRA, Medical Dictionary for Regulatory Activities, RTI, respiratory tract infection; SAE, serious adverse event; SMQ, Standardized MedDRA Query; UMEC, umeclidinium; VI, vilanterol.

moderate/severe exacerbation versus FF/VI and reduced the risk of these events versus both FF/VI and UMEC/VI in patients with symptomatic COPD and a history of exacerbations, though these reductions were not statistically significant. Furthermore, FF/UMEC/VI significantly improved lung function (as assessed by trough FEV₁), and there were trends for improved health-related quality of life (as assessed by SGRQ score response) versus both dual therapy comparators, and improved health-related quality of life (as assessed by CAT score response) versus FF/VI in this cohort. Given the small size of the China cohort and the fact that the trial was not specifically powered for between-treatment comparisons in this cohort, the results of the current analysis should be interpreted based on the similarity of the results relative to the overall ITT population.

As anticipated in a population of patients with a history of exacerbations¹⁸, a high proportion of patients experienced moderate/severe exacerbations during the trial. In the China cohort, FF/UMEC/VI reduced the annual rate of on-treatment moderate/severe exacerbations compared with FF/VI and, while this was not a significant reduction, it was consistent with the pattern in the overall ITT population. This improvement was of a similar direction and magnitude to the results in the overall ITT population. In contrast, there was no clear difference in the annual rate of moderate/severe exacerbations between FF/UMEC/VI and UMEC/VI among patients from China. This may be due to chance variation in the relatively small patient sample receiving UMEC/VI, as patients were randomized to FF/UMEC/VI, FF/VI, and UMEC/VI in a 2:2:1 ratio. Alternatively, it is worth noting that the Chinese

population had a slightly more severe disease presentation in terms of lung function and symptoms compared with the overall ITT population, while the exacerbation history profiles were similar, and <1% of the population were receiving LABA/LAMA therapy at baseline compared with 8% of the overall ITT population. Together, these factors may help to explain the slightly better performance of the dual bronchodilator in this population. Importantly, the treatment effects of both FF/UMEC/VI versus FF/VI and FF/UMEC/VI versus UMEC/VI on the time-to-first on-treatment moderate/severe exacerbation in the China cohort were similar to the results seen in the overall ITT population. Of note, rates of mild/moderate/severe COPD exacerbations and COPD exacerbations requiring systemic/oral corticosteroids were lowest in the FF/UMEC/VI group in the China cohort, as compared with FF/VI and UMEC/VI treatment groups. These results illustrate that ICS may have less impact on infective exacerbations treated with antibiotics but could play an important role in the prevention of inflammatory exacerbations that respond to oral corticosteroid use, which is consistent with a previous report¹⁹. Complex patterns of exacerbation data and prevention can occur between the three treatment regimens and this can be impacted by the way exacerbations are treated, including the preference for antibiotic or oral corticosteroid use in various countries. The proportion of patients experiencing severe exacerbations was higher in China than in the overall ITT population across all treatment arms. This difference between the two populations may be due to access to healthcare, as in China many people use hospital care as their primary means of healthcare access²⁰.

A number of studies have demonstrated the importance of wider measures of clinical efficacy on the patient experience of COPD^{21–23}. As such, other clinically relevant non-exacerbation measures were also analyzed in this China cohort and demonstrated results that were generally consistent with those seen in the overall ITT population. Firstly, statistically significant differences between FF/UMEC/VI and both FF/VI and UMEC/VI were shown for the mean change from baseline in trough FEV₁ at Week 52 in the China cohort. Furthermore, the proportion of SGRQ responders at Week 52 was highest in the FF/UMEC/VI group compared with either dual therapy in China, with between-treatment differences similar to those in the overall ITT population. In addition, the proportion of CAT responders at Week 52 in the China cohort was higher in the FF/UMEC/VI group compared with FF/VI; the proportion of CAT responders at Week 52 in the China cohort was similar between FF/UMEC/VI and UMEC/VI.

As previously reported, the safety profile of FF/UMEC/VI in the original IMPACT trial was in line with the profile of each of the individual components and that of the dual combinations FF/VI and UMEC/VI^{24,25}. This sub-analysis in the China cohort identified no new safety signals compared with the overall ITT population, with similar incidences of overall AEs, drug-related AEs, and SAEs across the three treatment groups. As expected, based on the class effect for ICS in patients with COPD¹, the incidence of pneumonia was highest in ICS-containing treatment groups. The incidences of reported pneumonia AESI were 13%, 13%, and 4% in the FF/UMEC/VI, FF/VI, and UMEC/VI groups in the China cohort compared with 8%, 7%, and 5%, respectively, in the overall ITT population. Due to the higher proportion of males, much lower BMI, and worse lung function, the China cohort had a higher baseline risk of pneumonia compared with the overall ITT population^{26,27}. It is worth noting that the IMPACT trial used a broad definition of pneumonia to ensure all pneumonia events were captured; serious adverse reports were adjudicated to determine the primary event. Reassuringly, incidences of these reports, primarily adjudicated to be pneumonia with or without evidence of COPD exacerbation, were consistent across these treatment groups in the two cohorts and of much lower magnitude compared with the reported pneumonia events (COPD exacerbation with evidence of pneumonia – China: FF/UMEC/VI 6%, FF/VI 5%, UMEC/VI 5%; overall ITT: FF/UMEC/VI 3%, FF/VI 3%, UMEC/VI 3%; pneumonia/RTI without COPD exacerbation – China: FF/UMEC/VI 2%, FF/VI <1%, UMEC/VI 0%; overall ITT: FF/UMEC/VI 2%, FF/VI 1%, UMEC/VI 1%). The results presented here are similar to those in the KRONOS study, which evaluated patients at low risk of pneumonia or exacerbation, of whom 23% were from China^{28,29}. In the KRONOS study, physician-reported pneumonia rates were higher than adjudicated rates in the overall study population, and the incidence of adjudicated pneumonia in the budesonide/glycopyrrolate/formoterol fumarate treatment arm of the China sub-group was higher than that observed in the overall population^{28,29}.

This study provides valuable data on the efficacy and safety of FF/UMEC/VI relative to FF/VI and UMEC/VI in a

population of patients from China with symptomatic COPD and a history of exacerbations. However, some limitations should be considered when interpreting the results. Firstly, and importantly, the analysis was carried out in only a small sample of patients, representing only 5% of the appropriately statistically powered overall ITT population. In addition, there were clear and distinct demographic differences between the China and overall ITT cohorts which may have affected the magnitude in results seen in drug efficacy and safety. Finally, differences in medical practice between China and the overall ITT population, including lower total use of oral/systemic corticosteroids and higher use of antibiotics, may limit the comparability of the China cohort and overall ITT population. Despite these limitations, our data demonstrate that FF/UMEC/VI is an effective treatment in China for patients with symptomatic COPD and a history of exacerbations. There are no inter-country differences in response to FF/UMEC/VI between patients with COPD in China and the overall ITT population, across multiple efficacy endpoints, providing valuable and relevant information for prescribing physicians in China.

Conclusions

While the IMPACT trial was not powered to demonstrate statistical significance for the primary endpoint of annual rate of on-treatment moderate/severe exacerbations in the China cohort, greater improvements in this endpoint were seen with FF/UMEC/VI versus FF/VI, similar to the results in the overall ITT population, although these improvements did not reach statistical significance. Furthermore, treatment with FF/UMEC/VI resulted in statistically significant improvements in lung function and clinically meaningful improvements in health-related quality of life compared with FF/VI and UMEC/VI. No new safety signals were identified in this cohort. These results highlight the favorable benefit/risk profile of FF/UMEC/VI single-inhaler triple therapy in China for patients with symptomatic COPD and a history of exacerbations.
