#### Abstract

Land Fill Gas (LFG) and Biogas are mixtures of methane $\left(\mathrm{CH}_{4}\right)$ / carbon dioxide $\left(\mathrm{CO}_{2}\right)$ that can be used as energy source in combustors. The presence of $\mathrm{CO}_{2}$ reduces the energy content per unit mass of these gases and negatively impacts the combustion stability. Laminar burning speeds of simulated LFG have been measured in this study.

The experiments were conducted in a constant volume cylindrical chamber with the aid of a Z-shaped Schlieren/shadowgraph system. Pressure rise data during the flame propagation were recorded through pressure transducer on the cylindrical chamber wall and were the main input into the thermodynamic model used to measure the laminar burning speed. A high-speed CMOS camera capable of taking pictures up to 40,000 frames per second was used to determine the cellularity of the flame.

Pictures of the $\mathrm{CH}_{4} /$ air/ $\mathrm{CO}_{2}$ flames for different equivalence ratios and carbon dioxide percentages were taken. As the $\mathrm{CO}_{2}$ mole fraction increased the flame is less prone to become cellular. Fuel rich mixtures are less likely to become cellular than fuel lean mixtures.

Experiments of $\mathrm{CH}_{4} /$ air/ $\mathrm{CO}_{2}$ mixtures have been conducted to simulate LFG/Biogas and laminar burning speeds were measured. The testing sets included three $\mathrm{CO}_{2}$ mole fractions $\mathrm{Xco}_{2}=0 \%, 20 \%$, and $30 \%$ at two initial pressures $\mathrm{P}_{\mathrm{i}}=1 \mathrm{~atm}$ and 2 atm . Moreover, the set covered three initial temperatures $\mathrm{T}_{\mathrm{i}}=298 \mathrm{~K}, 330 \mathrm{~K}$, and 360 K and three fuel air equivalence ratios of $\phi=0.8,1.0$, and 1.2.

The effect of $\mathrm{CO}_{2}$ on laminar burning speed was determined. As the $\mathrm{CO}_{2}$ mole fraction increased from 0 to $30 \%$ the laminar burning speeds decreased. Moreover, data show that the laminar burning speed of $\mathrm{CH}_{4} /$ air/ $\mathrm{CO}_{2}$ mixtures reduces with increasing pressure and increases with increasing temperature. The results show, the lowest laminar burning speed was measured at $\mathrm{Pi}=2 \mathrm{~atm}, \mathrm{Ti}=298 \mathrm{~K}, \phi=0.8$, and $\mathrm{Xco}_{2}=30 \%$.

## ACKNOWKEDGMENT

I would like to express my appreciation to Professor Hameed Metghalchi for his support and guidance during the learning journey at the combustion laboratory in Northeastern University. Moreover, I would like to extend my appreciation to the laboratory technician Kevin McCue and to my teammates Kevin Vien, Ziyu Wang, Guangying Yu, and Mohammed Alswat for their corporation and effort during the research process.

My parents provided the love and the support that is crucial for me to keep pursuing knowledge and dream big. My wife, Nada Alsaeidi, kept encouraging me to keep a good balance between knowledge and my social life. My sweetest daughter, Lana, kept the smile on my face with her jokes.

To my future me, never stop pursuing knowledge. Be wiser. Be smarter. Be happier.

## 1. Introduction

"In an ideal world, the design engineer would have available a complete set of measured values of all relevant properties. This is seldom the reality, however, and designers must often resort to (often crude) approximations of physical properties that are of questionable validity" [1].

The measurement of all relevant properties under all conditions is impossible [2]. Material properties are generally divided into two main categories physical and chemical properties. When designing a new process combination of these two properties are essential. The distinction between physical and chemical properties is not absolute but generally the chemical properties are related to the nature and magnitude of the intermolecular interactions. For example, detailed causes of the molecules collisions, complexing, and reacting. On the other hand, physical properties address the consequence of the chemical properties. The boiling temperature is a physical property that is the consequence of polarity, acidity or basicity (the latter are chemical properties) [2]. A physical can be measured or observed without changing the composition of the sample.

### 1.1. Background

Laminar burning speed (LBS) "is defined as the speed of the combustion wave normal to itself and relative to the unburned gas" [3]. It is a property that combines physical and chemical properties as well. The term physiochemical property is used in the literature to describe LBS [1]. There are many advantages of calculating the LBS, as Parsinejad [1] explains it in his thesis:
"The mass burning rates and burning speeds of homogenous fuel/oxygen/diluent gas mixtures are important both for developing and testing fluid dynamic and chemical kinetic models of hydrocarbon oxidation and for a wide range of direct practical applications in the fields of engines, burners, explosions, and chemical processors" [1]. There are many parameters that affect the LBS such as Temperature, Pressure, equivalence ratio, diluent, and fuel type.

### 1.2. Different Methods of Measuring Laminar Burning Speed (LBS)

There are two main approaches in measuring the LBS. Both are related to the position of the coordinates. If the coordinate system is fixed, then the flame will propagate away, hence the name propagating flame. If, on the other hand, the coordinate system is placed on top of the flame and moves with it the flame, it is said to be stationary. Flat flame burners, Bunsen burners, and stagnation burners all use stationary flame approach to measure LBS, whereas expanding spherical flames use the propagation approach.

In the stationary flat flame a jet of fuel enters the flame and for the stabilized flame the speed of the jet is equal to the burning speed of the flame. Many vertical channels are used in these experiments to make sure the flame is flat. The lack of consistence results and the difficulty of measuring LBS above $20 \mathrm{~cm} / \mathrm{s}$ are the two-main limitation of this approach [4]. The mass balance for flat flame burner is given by equation (1).

$$
\begin{equation*}
\rho_{\mathrm{u}} \mathrm{~S}_{\mathrm{L}} \mathrm{~A} \equiv \rho_{\mathrm{u}} \mathrm{v}_{\mathrm{u}} \mathrm{~A}=\rho_{\mathrm{b}} \mathrm{~V}_{\mathrm{b}} \mathrm{~A} \tag{1}
\end{equation*}
$$

If we consider hydrocarbon-air flame at 1 atm . the density ratio be comes $\frac{\rho_{\mathrm{u}}}{\rho_{\mathrm{b}}} \approx 7$ from this, we notice that $\frac{1}{7} \mathrm{v}_{\mathrm{b}} \approx \mathrm{S}_{\mathrm{L}}$.

In the propagating approach, the flame starts from one point and moves away from it. Pressure is constant for a period of time then the pressure increases. Using the constant pressure data, burning speed can be measured with need of stain correction for initial condition. As flame propagate pressure inside the vessel is increased. Burning speed can be measured as pressure is increased and LBS can be calculated for many states during one experiment.

### 1.3. Purpose of Research

The addition of $\mathrm{CO}_{2}$ to $\mathrm{CH}_{4}$ /air will be investigated experimentally to simulate the Land Fill Gas (LFG) content that is deliverable from municipal waste decommission. LFG can be used in internal combustion engines but the large quantities of $\mathrm{CO}_{2}$ effects the burning speed and stability of these engines [5]. Hinton and Stone [6] measured laminar burning speed of $\mathrm{CH}_{4} / \mathrm{air} / \mathrm{CO}_{2}$ mixtures and developed a correlation that is valid between $380 \mathrm{~K} \leq \mathrm{T}_{\mathrm{i}} \leq 520 \mathrm{~K}$, and 1 bar $\leq \mathrm{Pi} \leq 8$ bar [6]. This thesis will measure burning speed for larger range of $\mathrm{T}_{\mathrm{i}}, \mathrm{P}_{\mathrm{i}}, \phi$, and $\mathrm{Xco}_{2}$ mentioned in Table 1. In this study 54 initial conditions were chosen and experiments were made. Laminar burning speeds were measured along these 54 isotopes. Table 1 shows the test condition.

## 2. Laboratory Facilities

Northeastern combustion laboratory was established in 1995 by Ulinski, Elia, and Moore [1]. In 2005, Parsinejad [1] built liquid fuel injection system, which made it possible to vaporize the liquid fuel and inject it into either the cylindrical or spherical vessel [1]. In summer of 2016, leaks were reported so valves and tubes have been replaced by new ones.

### 2.1. Supply Systems

### 2.1.1. Gas Manifold

The Gas manifold system consists of five gas cylinders and two vacuum pumps. The gas cylinders include methane, air, nitrogen, hydrogen, and carbon monoxide. Since there are five inlet valves, the gas manifold can accommodate up to five different gases at a time. It's also possible to increase the gaseous input to more than five by simply connecting the valve connection to any number of desirable gas cylinders after each filling. The two vacuum pumps are identical of rotary vane type. The pumps are connected to $1 / 2$ HP motor by belts. These pumps are best suited for corrosive gases [7]. The manifold layout is shown in Figures 2 and 3. The pump suction line was upgraded from $1 / 4$ inch SS tube to $3 / 4$ inch hose, which reduced the vacuuming time.

Figure 1: Manifold layout

Figure 2: Gas Manifold

### 2.1.2. Liquid Injection

There are two separate liquid injection systems one for each combustion chamber. Each system consists of a small tank with capacity of $115 \mathrm{~cm}^{3}$ [8]. The fuel is manually poured into and a heated section to vaporize the liquid fuel. The tubes are of $1 / 8$-inch diameter. The fuel after vaporization is driven naturally to either the cylindrical or spherical chamber. The design of this system enabled Parisnejad [1] to calculate the laminar burning speed of JP-10 and JP-8.

### 2.2. Combustion Chambers

There are two types of combustion chambers in Northeastern university laboratory, cylindrical and spherical chambers. Both have the same gas manifold but separate liquid injection systems. The cylindrical chamber has glass windows on both sides, which allows to visually inspect the flame propagation and inspect cellularity as well. The spherical chamber on the other hand has ionization probes that would check the flame arrival time and gives signal to ensure that the flame touches the wall at the same time, this helps the experimenter know if the flame is buoyant or not.

### 2.2.1. Cylindrical Chamber

The cylindrical chamber shell and flanges are made of 316 SS , which has an inner diameter of 13.5 cm and 13 cm in length [1].The flanges hold the glass window to the shell by four bolts. The windows are made of 3.5 cm Pyrex glass that with stand pressures up to 50 atm . Figures 4 and 5 give very detailed dimensional drawings that were developed by Parisnejad [1].

Figure 3: Cylindrical combustion vessel with exploded view

Figure 4: Schematic diagram of the cylindrical vessel

Figure 5: Cylindrical Chamber Front View

Figure 6: Cylindrical Chamber Side view

### 2.2.2. Spherical Chamber

Unlike the cylindrical chamber the spherical chamber is made of 4140 steel that can withstand pressures of 425 atm when using 8 bolts for tightening [9]. Although Metghalchi [10] used a smaller thickness for his experiment back in 1980, the material was 4150 FM annealed alloy steel raising pressure limit to 680 atm . Figures 6 and 7 provides a detailed schematic which were developed by Parisnejad [1].

Figure 7: Spherical vessel with exploded view

Figure 8: Schematic diagram of spherical vessel

### 2.3. Data Acquisition System

The data acquisition system can be divided into three major categories pressure transducer on the vessel, Kistler pressure single amplifier, and analog to digital converter box. These three divisions are seen in figure 10. The pressure transducer enables the experimenter to fill the vessel to the desired partial pressures by reading from the strain gauges shown in Figure 3. Kistler amplifier converts the signals from $4-20 \mathrm{~mA}$ to $10 \mathrm{mV} / \mathrm{psia}$ which then processed via 16 -bit converter in the analog to digital converter [3]. The analog to digital box reads the voltage difference when the flame reaches the probes. Moreover, it begins recording the pressure time signals that is the main input to the code for calculating the laminar burning speed [3].

Figure 9: Data Acquisition system [3]

### 2.4. Flame Photography System (Schlieren System).

Although the spherical combustion chamber can be equipped with Schlieren system as seen in Mannaa [11], the laboratory in Northeastern University only has that system installed on the cylindrical chamber. Unlike the spherical chamber where the ionization probes are used to determine the flame arrival time, the flame can be observed and the arrival time can be read from pictures in the cylindrical chamber. This section aims to briefly describe the Schlieren system.

The six components shown in Figure 10 in the Schlieren system are light source, condenser lens, pinhole, two parabolic mirrors, and high speed camera. The light source is 10-Watt Halogen bulb connected to 185 mm black tube. The condenser of Thorlab Ac127-075-A-ML type that is placed 75 mm from pinhole and has the capability to focus the light to 3.6 um single spot [12]. The pinhole is 0.3 mm in diameter, which has the capability of sharpening the image. Figure 11 shows different sharpening techniques and their differences.

The two parabolic mirrors have focal length of 1524 mm and are located exactly one focal length from the pinhole or the camera. This exact distance insures that the mirrors projects parallel beam of light. The mirror that is closer to the light source projects the parallel light beam to the test area and to the second mirror. The second mirror intercepts the light and form a focused image [13]. The high-speed camera can capture up to 40000 frames/second, which allow us to visualize the different densities of the combustion mixture [12].

Figures 11 through 14 show the outwardly propagating flames that was taken by the highspeed camera. As percentage of $\mathrm{CO}_{2}$ is increased the flame becomes slower for the same condition.

Figure 11 show that for $\alpha=0 \%$ and $\phi=0.8$ the flame is faster than $\alpha=20 \%$ and $\alpha=30 \%$. The flame is fastest at fuel equivalence ratio of $\phi=1.0$ followed by $\phi=1.2$ for every test set. Figure 12 shows the cellularity of the flame at $\mathrm{P}_{\mathrm{i}}=2 \mathrm{~atm}$. The flame is highly cellular at the stochiometric ratio. Furthermore, as the percentage of $\mathrm{CO}_{2}$ is increased the flame becomes less cellular.

Figure 13 shows the flame is smooth at higher temperature and its only effected by the pressure. Figure 14 shows the effect of pressure on cellularity.

## 3. Experiment Procedures

### 3.1. Method of Partial Pressure

The desired partial pressure is calculated using the partial pressure method. In this study experiments were carried out for methane, carbon dioxide, and air mixtures.

For any hydrocarbon, of $\mathrm{C}_{x} \mathrm{H}_{y}$
$C_{x} H_{y}+\frac{\left(x+\frac{y}{4}\right)}{\varnothing}\left(O_{2}+3.76 N_{2}\right) \rightarrow x \mathrm{CO}_{2}+\frac{y}{2} \mathrm{H}_{2} \mathrm{O}+3.76 \frac{\left(x+\frac{y}{4}\right)}{\emptyset} N_{2}+\left(x+\frac{y}{4}\right)\left(\frac{1}{\emptyset}-1\right) O_{2}$

For $\mathrm{CH}_{4} / \mathrm{CO}_{2}$ mixture, we have two fuels we need to add $\alpha$ which is the percentages of $\mathrm{CO}_{2}$ in the mixture.
$\emptyset\left[\alpha \mathrm{CO}_{2}+(1-\alpha) \mathrm{CH}_{4}\right]+2(1-\alpha)\left(\mathrm{O}_{2}+3.76 \mathrm{~N}_{2}\right) \rightarrow$ Products

$$
\begin{equation*}
\mathrm{X}_{\mathrm{i}}=\frac{\mathrm{N}_{\mathrm{i}}}{\mathrm{~N}_{\text {Total }}} \tag{4}
\end{equation*}
$$

$$
\mathrm{X}_{\mathrm{CO} 2}=\frac{\mathrm{N}_{\mathrm{CO} 2}}{\mathrm{~N}_{\text {Total }}}=\frac{\emptyset \alpha}{\emptyset \alpha+\emptyset(1-\alpha)+9.52(1-\alpha)}
$$

$$
\begin{equation*}
X_{\mathrm{CH} 4}=\frac{\mathrm{N}_{\mathrm{CO} 2}}{\mathrm{~N}_{\text {Total }}}=\frac{\emptyset(1-\alpha)}{\emptyset \alpha+\emptyset(1-\alpha)+9.52(1-\alpha)} \tag{6}
\end{equation*}
$$

$$
\begin{array}{r}
\mathrm{X}_{\text {Air }}=\frac{\mathrm{N}_{\text {Air }}}{\mathrm{N}_{\text {Total }}}=\frac{9.52(1-\alpha)}{\emptyset \alpha+\emptyset(1-\alpha)+9.52(1-\alpha)} \\
\mathrm{P}_{\mathrm{i}}=\mathrm{X}_{\mathrm{i}} \mathrm{P}_{\text {total }} \\
\mathrm{P}_{\mathrm{CO}_{2}}=\mathrm{X}_{\mathrm{CO}_{2}} \mathrm{P}_{\text {total }} \\
\mathrm{P}_{\mathrm{CH}_{4}}=\mathrm{X}_{\mathrm{CH}_{4}} \mathrm{P}_{\text {total }} \\
\mathrm{P}_{\mathrm{Air}}=\mathrm{X}_{\text {Air }} \mathrm{P}_{\text {total }} \tag{11}
\end{array}
$$

### 3.2. Preheating and Filling Up

If the experiments were to be carried out at room temperature the filling can be started when the vacuum reading is around 100 millitorr. Otherwise, the chamber must be heated to the desired initial temperature. The process of heating is very important and it will take time to reach steady state. The experimenter start by filling the vessel with the lowest partial pressure, which is $\mathrm{CO}_{2}$ in this study. Then $\mathrm{CH}_{4}$ is filled since its partial pressure is higher than that of $\mathrm{CO}_{2}$. Lastly, the air is filled and the total pressure must be equal to the initial pressure.

### 3.3. Igniting and Post-Processing.

After the filling is complete the experimenter starts by switching the ignition box capacitor and opening the LabView VI to start igniting the mixture. The waiting time between filling and igniting is very important in order to give the mixture enough time to mix evenly.

The LabView VI will record the Pressure time trace. Figures 18 through 20 show pressure vs time trace. Figures 17 through 19 show the raw data after the experiment. The raw data is further processed to include only the pressure time trace for smooth flames or before it hits the walls of the vessel if the flame is not cellular. In Figure 17, the little notch at the stochiometric mixture indicate that the flame has hit the wall. Figure 18 shows the effect of the addition of $20 \% \mathrm{CO}_{2}$ on the slope of the pressure time trace.

Figure 15: Pressure vs time for mixture of methane/air, at $T_{i}=\mathbf{2 9 8} \mathbf{K}$, and $P_{i}=1 \mathrm{~atm}$ for three different fuel equivalence ratios of $0.8,1.0$, and 1.2

Figure 16: Pressure vs time for mixture of methane/air/ $\mathbf{2 0 \%}$ carbon dioxide, at $\mathrm{T}_{\mathrm{i}}=\mathbf{2 9 8} \mathrm{K}$, and $\mathbf{P}_{\mathrm{i}}=\mathbf{1}$ atm for three different fuel equivalence ratios of $0.8,1.0$, and 1.2

Figure 17: Pressure vs time for mixture of methane/air/ $\mathbf{3 0 \%}$ carbon dioxide, at $T_{i}=\mathbf{2 9 8} \mathrm{K}$, and $\mathrm{P}_{\mathrm{i}}=1 \mathrm{~atm}$ for three different fuel equivalence ratios of $0.8,1.0$, and 1.2

## 4. Thermodynamic Model

A thermodynamic model has been developed to calculate burning speed from pressure measurement. In the model burning gas is in the center of vessel surrounded by reaction sheet, pre-heat flame zone, core unburned gas and boundary layer gas touching the vessel as shown in Figure 18. In the spherical flames measured pressure is used along with the mass, energy balance, ideal gas equations to calculate the temperature distribution in the unburned and burned gas region. Also, the mass fraction of the burned gas can be calculated. In the model, all gases behave as ideal gases with the following equations.

$$
\begin{equation*}
p v=R T \tag{12}
\end{equation*}
$$

Figure 18:Schematic of three different zones in the thermodynamics model

Where, p is the pressure which is measured within the chamber, v is the specific volume, R is the specific gas constant, and T is the temperature.

The mass balance equation for the burned and unburned gas region is

$$
\begin{equation*}
\mathrm{m}=\mathrm{m}_{\mathrm{b}}+\mathrm{m}_{\mathrm{u}}=\rho_{\mathrm{b}} \mathrm{~V}_{\mathrm{b}}+\rho_{\mathrm{u}} \mathrm{~V}_{\mathrm{u}}=\mathrm{p}_{\mathrm{i}}\left(\mathrm{~V}_{\mathrm{c}}-\mathrm{V}_{\mathrm{e}}\right) / \mathrm{RT}_{\mathrm{i}} \tag{13}
\end{equation*}
$$

where $m$ is the total mass of the chamber, $m_{b}$ is the mass of the burned gas zone, $m_{u}$ is the mass of the unburned gas zone, $V_{c}$ is the volume of the chamber and $V_{e}$ is the volume of the spark electrodes. In this equation, the subscript i denotes the initial conditions, and subscripts b and $u$ represent the burned gas and unburned conditions respectively. And $\rho$ is the average density and $V$ is the volume of the gas. The total volume of the gas in the combustion chamber is

$$
\begin{equation*}
V_{i}=V_{c}-V_{e}=V_{b}+V_{u} \tag{14}
\end{equation*}
$$

where

$$
\begin{equation*}
\mathrm{V}_{\mathrm{b}}=\int_{0}^{\mathrm{m}_{\mathrm{b}}} \mathrm{v}^{\prime}\left(\mathrm{T}^{\prime}, \mathrm{p}\right) \mathrm{dm} \mathrm{~m}^{\prime}=\int_{0}^{\mathrm{m}_{\mathrm{b}}} \mathrm{v}_{\mathrm{bs}}^{\prime}\left(\mathrm{T}^{\prime}, \mathrm{p}\right) \mathrm{dm}^{\prime}-\mathrm{V}_{\mathrm{eb}} \tag{15}
\end{equation*}
$$

$\mathrm{V}_{\mathrm{b}}$ is the volume of the burned gas, $\mathrm{V}_{\mathrm{bs}}$ is the specific volume of isentropically compressed burned gas.

$$
\begin{equation*}
\mathrm{V}_{\mathrm{eb}}=\int_{\mathrm{eb}}\left(\mathrm{v}_{\mathrm{bs}}^{\prime}-\mathrm{v}^{\prime}\right) \mathrm{dm}^{\prime} \tag{16}
\end{equation*}
$$

$\mathrm{V}_{\mathrm{eb}}$ is the displacement volume of the electrode boundary layers.

$$
\begin{equation*}
\mathrm{V}_{\mathrm{u}}=\int_{\mathrm{m}_{\mathrm{b}}}^{\mathrm{m}} \mathrm{v}^{\prime}\left(\mathrm{T}^{\prime}, \mathrm{p}\right) \mathrm{dm}^{\prime}=\mathrm{m}\left(1-\mathrm{x}_{\mathrm{b}}\right) \mathrm{v}_{\mathrm{us}}-\mathrm{V}_{\mathrm{wb}}-\mathrm{V}_{\mathrm{ph}} \tag{17}
\end{equation*}
$$

$V_{u}$ is the volume of the unburned gas, $x_{b}=m_{b} / m$ is the burned gas mass fraction, $v_{u s}$ is the specific volume of the isentropically compressed unburned gas,

$$
\begin{equation*}
\mathrm{V}_{\mathrm{wb}}=\int_{\mathrm{wb}}\left(\mathrm{v}_{\mathrm{us}}-\mathrm{v}^{\prime}\right) \mathrm{dm}^{\prime} \tag{18}
\end{equation*}
$$

$\mathrm{V}_{\mathrm{wb}}$ is the displacement volume of the wall boundary layer, and

$$
\begin{equation*}
\mathrm{V}_{\mathrm{ph}}=\int_{\mathrm{ph}}\left(\mathrm{v}_{\mathrm{us}}-\mathrm{v}^{\prime}\right) \mathrm{dm}^{\prime} \tag{19}
\end{equation*}
$$

$\mathrm{V}_{\mathrm{ph}}$ is the displacement volume of the preheat zone ahead of the reaction layer.

The energy balance equation is given by

$$
\begin{equation*}
E_{i}-Q_{e}-Q_{w}-Q_{r}=E_{b}+E_{u} \tag{20}
\end{equation*}
$$

where $E_{i}$ is the initial energy of the gas, $Q_{e}$ is the conductive energy loss to the electrodes, $Q_{w}$ is the energy loss to the wall, $\mathrm{Q}_{\mathrm{r}}$ is the radiation energy loss,

$$
\begin{equation*}
\mathrm{E}_{\mathrm{b}}=\int_{0}^{\mathrm{m}_{\mathrm{b}}} \mathrm{e}^{\prime}\left(\mathrm{T}^{\prime}, \mathrm{p}\right) \mathrm{dm}^{\prime}=\int_{0}^{\mathrm{m}_{\mathrm{b}}} \mathrm{e}_{\mathrm{bs}}^{\prime}\left(\mathrm{T}^{\prime}, \mathrm{p}\right) \mathrm{dm}^{\prime}-\mathrm{E}_{\mathrm{eb}} \tag{21}
\end{equation*}
$$

$E_{b}$ is the energy of the burned gas, $e_{b s}$ is the specific energy of isentropically compressed burned gas,

$$
\begin{equation*}
\mathrm{E}_{\mathrm{eb}}=\int_{\mathrm{eb}}\left(\mathrm{e}_{\mathrm{bs}}^{\prime}-\mathrm{e}^{\prime}\right) \mathrm{dm}^{\prime} \tag{22}
\end{equation*}
$$

$\mathrm{E}_{\mathrm{eb}}$ is the energy defect of the electrode boundary layer,

$$
\begin{equation*}
E_{u}=\int_{m_{b}}^{m} e^{\prime}\left(T^{\prime}, p\right) d m^{\prime}=m\left(1-x_{b}\right) e_{u s}-\left(E_{w b}+E_{p h}\right) \tag{23}
\end{equation*}
$$

$E_{u}$ is the energy of the unburned gas, $e_{u s}$ is the specific energy of the isentropically compressed unburned gas,

$$
\begin{equation*}
\mathrm{E}_{\mathrm{wb}}=\int_{\mathrm{wb}}\left(\mathrm{e}_{\mathrm{us}}-\mathrm{e}^{\prime}\right) \mathrm{dm}^{\prime} \tag{24}
\end{equation*}
$$

$E_{w b}$ is the energy defect of the wall boundary, and

$$
\begin{equation*}
\mathrm{E}_{\mathrm{ph}}=\int_{\mathrm{ph}}\left(\mathrm{e}_{\mathrm{us}}-\mathrm{e}^{\prime}\right) \mathrm{dm}^{\prime} \tag{25}
\end{equation*}
$$

$\mathrm{E}_{\mathrm{ph}}$ is the energy defect of the preheat layer.

The definition of enthalpy

$$
\begin{equation*}
\mathrm{h}=\mathrm{h}_{\mathrm{f}}+\int_{0}^{\mathrm{T}} \mathrm{C}_{\mathrm{p}} \mathrm{dT}=\mathrm{e}+\mathrm{pv} \tag{26}
\end{equation*}
$$

Using ideal gas assumption, constant specific heat

$$
\begin{align*}
& e-h_{f}=\int_{0}^{T} C_{p} d T-p v=C_{p} T-p v  \tag{27}\\
& C_{p}-C_{v}=R  \tag{28}\\
& \frac{C_{p}}{C_{v}}=\gamma \tag{29}
\end{align*}
$$

Combining Equation (26) with Equations (27) and (28), we get equation (29)
$\mathrm{e}-\mathrm{h}_{\mathrm{f}}=\mathrm{pv} /(\gamma-1)$
where $h_{f}$ is the enthalpy of formation of the gas at zero degrees Kelvin and $\gamma$ is the specific heat ratio. By this relation, Equations (22), (24), and (25) can be written as

$$
\begin{align*}
& \mathrm{E}_{\mathrm{eb}}=\int_{\mathrm{eb}}\left(\frac{\mathrm{p}_{\mathrm{bs}}}{\mathrm{r}_{\mathrm{b}}-1}+\mathrm{h}_{\mathrm{f}}-\left(\frac{\mathrm{pv}^{\prime}}{\mathrm{r}_{\mathrm{b}}-1}+\mathrm{h}_{\mathrm{f}}\right)\right) \mathrm{dm}^{\prime}  \tag{31}\\
& \mathrm{E}_{\mathrm{eb}}=\frac{\mathrm{p} \int_{\mathrm{eb}}\left(\mathrm{v}_{\mathrm{bs}}-\mathrm{v}^{\prime}\right) \mathrm{dm}^{\prime}}{\gamma_{\mathrm{b}}-1}=\mathrm{p} \mathrm{~V}_{\mathrm{eb}} /\left(\gamma_{\mathrm{b}}-1\right)  \tag{32}\\
& E_{w b}=\int_{w b}\left(\frac{p_{\mathrm{us}}}{r_{u}-1}+h_{f}-\left(\frac{\mathrm{pv}^{\prime}}{r_{u}-1}+h_{f}\right)\right) d m^{\prime}  \tag{33}\\
& E_{w b}=\frac{p \int_{w b}\left(v_{u s}-v^{\prime}\right) \mathrm{dm}^{\prime}}{\gamma_{\mathrm{u}}-1}=\mathrm{p} V_{\mathrm{wb}} /\left(\gamma_{\mathrm{u}}-1\right)  \tag{34}\\
& \mathrm{E}_{\mathrm{ph}}=\int_{\mathrm{ph}}\left(\frac{\mathrm{pv}_{\mathrm{us}}}{\mathrm{r}_{\mathrm{u}}-1}+\mathrm{h}_{\mathrm{f}}-\left(\frac{\mathrm{pv}^{\prime}}{\mathrm{r}_{\mathrm{u}}-1}+\mathrm{h}_{\mathrm{f}}\right)\right) \mathrm{dm}^{\prime}  \tag{35}\\
& \mathrm{E}_{\mathrm{ph}}=\frac{\mathrm{p} \int_{\mathrm{ph}}\left(\mathrm{v}_{\mathrm{us}}-\mathrm{v}^{\prime}\right) \mathrm{dm}^{\prime}}{\gamma_{\mathrm{u}}-1}=\mathrm{p} V_{\mathrm{ph}} /\left(\gamma_{\mathrm{u}}-1\right) \tag{36}
\end{align*}
$$

the compression work terms on the boundary layer may be neglected and the resulting equations are

$$
\begin{gather*}
\mathrm{Q}_{\mathrm{e}}=\frac{\mathrm{pV}}{\gamma_{\mathrm{eb}}-1}=\mathrm{E}_{\mathrm{eb}}  \tag{37}\\
\mathrm{Q}_{\mathrm{w}}=\frac{\mathrm{pv}_{\mathrm{wb}}}{\gamma_{\mathrm{u}}-1}=\mathrm{E}_{\mathrm{wb}} \tag{38}
\end{gather*}
$$

The radiation energy loss from the burned gas was calculated using

$$
\begin{equation*}
\mathrm{Q}_{\mathrm{r}}=\int_{0}^{\mathrm{t}} \dot{\mathrm{Q}}_{\mathrm{r}}\left(\mathrm{t}^{\prime}\right) \mathrm{dt}^{\prime}=4 \alpha_{\mathrm{p}} \mathrm{~V}_{\mathrm{b}} \sigma \mathrm{~T}_{\mathrm{b}}^{4} \tag{39}
\end{equation*}
$$

where $\alpha_{p}$ is the Planck mean absorption coefficient and $\sigma$ is the Stefan-Boltzman constant.

Finally, combining Equations (14), (15), and (17) gives

$$
\begin{equation*}
\int_{0}^{\mathrm{x}_{\mathrm{b}}}\left(\mathrm{v}_{\mathrm{bs}}\left(\mathrm{~T}^{\prime}, \mathrm{p}\right)-\mathrm{v}_{\mathrm{us}}\right) \mathrm{dx} \mathrm{x}^{\prime}=\mathrm{v}_{\mathrm{i}}-\mathrm{v}_{\mathrm{us}}+\left(\mathrm{V}_{\mathrm{eb}}+\mathrm{V}_{\mathrm{wb}}+\mathrm{V}_{\mathrm{ph}}\right) / \mathrm{m} \tag{40}
\end{equation*}
$$

and combining Equations (11), (12), and (14) gives

$$
\begin{align*}
& \int_{0}^{\mathrm{x}_{\mathrm{b}}}\left(\mathrm{e}_{\mathrm{bs}}\left(\mathrm{~T}^{\prime}, \mathrm{p}\right)-\mathrm{e}_{\mathrm{us}}\right) \mathrm{dx}= \\
& \mathrm{e}_{\mathrm{i}}-\mathrm{e}_{\mathrm{us}}+\frac{\frac{\mathrm{pv}_{\mathrm{ph}}}{\gamma_{\mathrm{u}}-1}-Q_{\mathrm{r}}}{\mathrm{~m}}-\mathrm{A}_{\mathrm{wb}}\left(\mathrm{p} \delta_{\mathrm{wb}}-\int_{0}^{\mathrm{p}} \delta_{\mathrm{wb}} \mathrm{dp}\right)-\mathrm{A}_{\mathrm{eb}}\left(\mathrm{p} \delta_{\mathrm{eb}}-\int_{0}^{\mathrm{p}} \delta_{\mathrm{eb}} \mathrm{dp}\right) \tag{41}
\end{align*}
$$

where $v_{i}=\left(V_{c}-V_{e}\right) / m$ and $e_{i}=E_{i} / m$ are the initial specific volume and energy of the unburned gas in the chamber.

The above two Equations (41) and (42) have been solved for two unknowns: burned mass fraction, $\mathrm{x}_{\mathrm{b}}(\mathrm{t})$, and the burned gas temperature of the last layer, $\mathrm{T}_{\mathrm{b}}(\mathrm{r}, \mathrm{t})$. Given pressure, $\mathrm{p}(\mathrm{t})$, as a function of time, they can be solved numerically using Newton-Raphson method to obtain the burned mass fraction as a function of time and temperature distribution.

Laminar burning speed can be defined as

$$
\begin{equation*}
S_{u}=\frac{\dot{m i}_{\mathrm{b}}}{\rho_{\mathrm{u}} A_{\mathrm{b}}}=\frac{\mathrm{mx}_{\mathrm{b}}}{\rho_{\mathrm{u}} A_{\mathrm{b}}} \tag{42}
\end{equation*}
$$

where

$$
\begin{gather*}
\mathrm{A}_{\mathrm{b}}=4 \pi \mathrm{r}_{\mathrm{b}}^{2}-2 \pi \mathrm{r}_{\mathrm{e}}^{2}  \tag{43}\\
\mathrm{~V}_{\mathrm{b}}=\frac{4}{3} \pi \mathrm{r}_{\mathrm{b}}^{3}-2 \pi \mathrm{r}_{\mathrm{e}}^{2} \mathrm{r}_{\mathrm{b}} \tag{44}
\end{gather*}
$$

$A_{b}$ is the area of a sphere having a volume equal to that of the burned gas and $x_{b}(t)$ can be solve from the previous equations. This expression is valid for smooth, cracked, or wrinkled flames of any shape. Thus, laminar burning speed can be calculated from equation 42.

## 5. Results and Discussion

Experiments were conducted for the 54 conditions in Table 1 and laminar burning speeds were measured for smooth flames and with radii larger than 4 cm . Figures from 22 through 39 present the measured LBS for $\phi=0.8,1.0$, and 1.2 at a given initial condition. Each condition show results of LBS for isentrope.

It is noticed from Figures 22 through 24 that the LBS decreases as the percentage of carbon dioxide is increased. For example, for $\mathrm{Xco}_{2}=0 \%$ and $\phi=1.0$, LBS is measured to be 38 $\mathrm{cm} / \mathrm{s}$ vs $29 \mathrm{~cm} / \mathrm{s}$ at $\mathrm{Xco}_{2}=20 \%$ and $23 \mathrm{~cm} / \mathrm{s}$ for $\mathrm{Xco}_{2}=30 \%$. The decrease of LBS between $\mathrm{Xco}_{2}=0 \%$ and $\mathrm{Xco}_{2}=20 \%$ is $9 \mathrm{~cm} / \mathrm{s}$ whereas between $\mathrm{Xco}_{2}=20 \%$ and $\mathrm{Xco}_{2}=30 \%$ the decrease is only $6 \mathrm{~cm} / \mathrm{s}$.

When $\phi=1.2$ the decrease is almost the same between $\mathrm{Xco}_{2}=0 \%$ and $\mathrm{Xco}_{2}=20 \%$. (i.e., LBS is $35 \mathrm{~cm} / \mathrm{s}$ for $\mathrm{Xco}_{2}=0 \%$ and $27 \mathrm{~cm} / \mathrm{s}$ for $\mathrm{Xco}_{2}=20 \%$ with $8 \mathrm{~cm} / \mathrm{s}$ decrease). Moreover, the decrease is exactly $6 \mathrm{~cm} / \mathrm{s}$ for $\phi=1.2$ between $\mathrm{Xco}_{2}=20 \%$ and $\mathrm{Xco}_{2}=30 \%$ with measured LBS of $27 \mathrm{~cm} / \mathrm{s}$ and $21 \mathrm{~cm} / \mathrm{s}$ respectively. The decrease for $\phi=0.8$ between $\mathrm{Xco}_{2}=0 \%$ and $\mathrm{Xco}_{2}=$ $20 \%$ is also $9 \mathrm{~cm} /$ s. (i.e., from $30 \mathrm{~cm} / \mathrm{s}$ to $21 \mathrm{~cm} / \mathrm{s}$ ). However, the decrease between $\mathrm{Xco}_{2}=20 \%$ and $\mathrm{Xco}_{2}=30 \%$ is only $2 \mathrm{~cm} / \mathrm{s}$ but it's similar to the decrease of the measurements reported in [3].

As $T_{i}$ is increased from 298 K to 330 K , the LBS decrease between different diluent concentration is almost maintained for $\phi=1.2$ and $\phi=0.8$ (i.e., the decrease between $\mathrm{Xco}_{2}=0 \%$ and $\mathrm{Xco}_{2}=20 \%$ for $\phi=0.8$ is $7 \mathrm{~cm} / \mathrm{s}$ from $35 \mathrm{~cm} / \mathrm{s}$ to $28 \mathrm{~cm} / \mathrm{s}$ and the decrease is $6 \mathrm{~cm} / \mathrm{s}$ between $\mathrm{Xco}_{2}=20 \%$ and $\mathrm{Xco}_{2}=30 \%$ for $\phi=0.8$ from $28 \mathrm{~cm} / \mathrm{s}$ to $22 \mathrm{~cm} / \mathrm{s}$ respectively). For $\phi=1.0$ the decrease is about $5 \mathrm{~cm} / \mathrm{s}$ between $\mathrm{Xco}_{2}=0 \%$ and $\mathrm{Xco}_{2}=20 \%$ with measured LBS of $42 \mathrm{~cm} / \mathrm{s}$ and $27 \mathrm{~cm} / \mathrm{s}$ respectively.

The decrease of LBS between $\mathrm{Xco}_{2}=0 \%$ and $\mathrm{Xco}_{2}=20 \%$ becomes smaller as $\mathrm{T}_{\mathrm{i}}$ increased from 330 K to 360 K , as shown in Figures 28 through 30. For example, when $\phi=0.8$ and $\mathrm{Xco}_{2}=0 \%$ LBS is measured to be $34 \mathrm{~cm} / \mathrm{s}$ compared to $29 \mathrm{~cm} / \mathrm{s}$ when $\mathrm{Xco}_{2}=20 \%$.

Figures 31 through 39 represent LBS for $\mathrm{T}_{\mathrm{i}}=298 \mathrm{~K}, 330 \mathrm{~K}$, and 360 K for higher initial pressure of 2 atm . The effect of increasing the pressure is noticeable in decreasing LBS but the effect of increasing the $\mathrm{CO}_{2}$ percentage is still applicable as it decreases the LBS as well. For example, when $\phi=1.0$ and $\mathrm{Xco}_{2}=0 \%$ LBS are measured to be $29 \mathrm{~cm} / \mathrm{s}, 34 \mathrm{~cm} / \mathrm{s}$, and $39 \mathrm{~cm} / \mathrm{s}$ for $\mathrm{T}_{\mathrm{i}}=298 \mathrm{~K}, 330 \mathrm{~K}$, and 360 K respectively. And when $\phi=1.0$ and $\mathrm{Xco}_{2}=20 \% \mathrm{LBS}$ are measured to be $23 \mathrm{~cm} / \mathrm{s}, 27 \mathrm{~cm} / \mathrm{s}$, and $35 \mathrm{~cm} / \mathrm{s}$ for $\mathrm{T}_{\mathrm{i}}=298 \mathrm{~K}, 330 \mathrm{~K}$, and 360 K respectively.

## 6. Conclusion and Recommendation

The laminar burning speed and the flame cellularity of spherically expanding flames of $\mathrm{CH}_{4} / \mathrm{air} / \mathrm{CO}_{2}$ mixtures that have three different carbon dioxide concentrations $(0 \%, 20 \%$ and $30 \%$ ) have been studied for three fuel air equivalence ratios of $\phi=0.8,1.0$, and 1.2. Moreover, three initial temperatures $\mathrm{T}_{\mathrm{i}}=298 \mathrm{~K}, 330 \mathrm{~K}$, and 360 K respectively as well as two initial pressures of $\mathrm{P}_{\mathrm{i}}=1 \mathrm{~atm}$ and 2 atm . Laminar burning speed measurements covered a wide range of temperatures and pressures up to 430 K and 3.6 atm . Laminar burning speeds of stochiometric mixtures ratios are measured to be the fastest followed by $\phi=1.2$ and $\phi=0.8$. Moreover, LBS is directly proportional to temperature and inversely proportional to pressure. The flame become cellular for $\mathrm{P}_{\mathrm{i}}=2 \mathrm{~atm}$ and $\phi=1.0$ and less cellular for $\phi=1.2$. The flame cellularity is delayed as the percentage of carbon dioxide is increased.

Future researchers can simulate Biogas and LFG more accurately if the small percentages of carbon monoxide is considered. Moreover, experiment at higher pressures and temperatures than 430 K and 2 atm . can be done to measure the laminar burning speeds of the simulated land fill gas over large range of temperatures, pressures, and fuel air equivalence ratios.
