## Declaration

The work described in this thesis is the work of the author unless indicated otherwise and has not previously been submitted to this or any other university for any other degree. The research was carried out between October 2009 and September 2012, under the supervision of Professor Andy Whiting.

## Statement of Copyright

The copyright of this thesis rests with the author. No quotations from it should be published without prior consent and information derived from it should be acknowledged.

#### Abstract

Three new modes of reactivity are reported between the reaction of an imine, but-3-en-2-ones and a Lewis acid. These are formal [2+2+2]-, [1+2+1+2]- and [4+2]cycloadditions, deriving 1,1'-(1,2-dihydropyridine-3,5-diyl)diethanones A, 1,1'-(1,4-dihydropyridine-3,5-diyl)diethanones $\mathbf{B}$ and piperidin-4-ones $\mathbf{C}$ and $\mathbf{D}$ respectively. The $[2+2+2]$ - and $[1+2+1+2]$-cycloadditions proceed when $\mathrm{R}^{3}=\mathrm{LG}$ (leaving group), with the $[1+2+1+2]$-pathway dominating when the imine is easily hydrolysed within the reaction conditions. When $\mathrm{R}^{3} \neq \mathrm{LG}$, the cycloaddition proceeds through different [4+2]-mechanistic pathways, dependent on how good a Michael acceptor the enone is. 

In addition, this work presents the asymmetric synthesis of aminoboronic acid $\mathbf{E}$. Its activity as a bifunctional organocatalyst was explored and it was found that partly due to boron-nitrogen chelation, this catalyst was inactive within the aza-Diels-Alder, aldol and Mannich reactions, although active within the Michael reaction. Nonetheless, this catalyst was found to be active when performing the aldol reaction in high concentrations, in order to predominantly afford double aldol products.

E

## Acknowledgements

I would first like to sincerely thank my academic supervisor Prof. Andy Whiting for taking me on this exciting project and for his continued enthusiasm, motivation and support during my PhD .

Secondly, I would like to thank Merck \& Co. (formerly Schering-Plough, Newhouse, UK) for funding this project, and in particular my respective industrial supervisors Dr. Hong Shen and Dr. Takao Kiyoi for their eager support and assistance along the way.

In addition, I am grateful for the analytical services, both at Durham University and Merck (Rahway, US), including NMR spectroscopy, mass spectrometry, chromatography and elemental analysis. In particular, I would like to thank Dr. Andrei Batsanov for performing the X-ray crystallography, Dr. Paul Yeo for running the biological experiments, and the EPSRC National Mass Spectrometry Service at Swansea for performing mass spectrometry on some of the more sensitive samples.

A special recognition goes to everyone in the Whiting group and Merck labs past and present, along with all the friends I have made during my PhD , for making my time at Durham an enjoyable experience and for all the help I have received. This includes (although not limited to) Fathia, Andy, Ben, Vicki, Hayley, Nim, Garr-Layy, Adam, Farhana and Hesham. In particular, I would like to express thanks to Craig and Irene for sharing their experience and knowledge, with a big thank-you going to Dr. Alex Gehre for proofreading this thesis.

Finally, I am forever indebted to my family for their unwavering love and support throughout my studies.

Chapter 1:
INTRODUCTION

## 1. INTRODUCTION

The piperidine ring system ${ }^{1}$ is widely found within nature ${ }^{2}$ with the natural products possessing these ring systems showing a wide range of biological activities. ${ }^{3}$ Consequently, there is considerable interest in these types of compounds ${ }^{4}$ due to their medicinal properties ${ }^{5}$ and as a result, many analogues have been developed as therapeutic agents. ${ }^{6}$ One way of constructing these six-membered rings is via an aza-Diels-Alder reaction involving an imino dienophile and a conjugated diene. The cycloaddition can be either a relatively concerted process with less polarised dienes. ${ }^{7}$ However, when using more electron rich dienes (i.e. oxygenated dienes or enone equivalents), only a formal Diels-Alder process occurs, generally assisted by an activating agent such as a Lewis acid $^{8}$ or an organocatalyst. ${ }^{9}$ In this introduction, we investigate the development of the formal cycloaddition of imino dienophiles with highly electron rich dienes and enones to derive tetrahydropiperidine frameworks and compare the different reaction conditions, reagents and applications as well as the mechanisms which are operating.

## 1.1 aza-Diels-Alder Reaction

The Diels-Alder reaction is a classic example of a concerted pericyclic cycloaddition between a conjugated diene 1 and a dienophile 2 in order to form a cyclohexene ring 3 (Equation 1). Otto Diels and his student Kurt Alder first documented this simple reaction in 1928, which instantaneously opened up new gateways in organic synthesis and quickly became widely used. As a result, they were awarded the 1950 Nobel Prize in Chemistry "for their discovery and development of the diene synthesis" (Nobel Foundation).

## Equation 1

The fundamental difference in the aza-Diels-Alder reaction is the exchange of a carbon for a nitrogen atom (typically in the dienophile), resulting in the formation of a six-membered nitrogen-containing tetrahydropyridine (or equivalent). The aza-DielsAlder reaction may occur in a concerted manner, however, in many cases, the reaction may be better thought of as a step-wise Mannich followed by an intramolecular Michael reaction. Both concerted and Mannich-Michael processes might be assisted by the use of catalysts, including Lewis acids and organocatalysts, and this is the subject of this project.

The Lewis acid-catalysed approach to achieving overall aza-Diels-Alder addition relies upon activating the imine, which in turn activates the initial Mannich reaction to proceed. In contrast, the organocatalytic approach is generally based upon activating the diene (in the form of an $\alpha, \beta$-unsaturated ketone) through the formation of an enamine. As such, the organocatalytic process tends to involve chiral pyrrolidinederived systems which permit asymmetric induction to be developed, with the simplest and most commonly available catalyst being L-proline. ${ }^{10}$

Earlier research has tended to concentrate on Lewis acid-catalysis ${ }^{11}$ due to their relative availability and versatility. However, in recent years there has been a shift towards organocatalysis because it is possible to achieve high enantioselective transformations. ${ }^{12}$ This shift in concentration has been brought about by the increasing importance of organocatalysis in the last decade, ${ }^{13}$ and our understanding of the underlying concepts that has enabled application on different systems, ${ }^{14}$ including the aza-Diels-Alder reaction.

### 1.2 Asymmetric Construction using Lewis acids

In 1974, Danishefsky et al. reported on "a useful diene for the Diels-Alder reaction", where they explained the formation of an electron rich diene in the form of a silyl enol ether 4, suggesting that it can be used as an activated diene in the Diels-Alder reaction to mask carbonyl groups. This compound has ever since been known as the Danishefsky diene 4. ${ }^{15}$ Over the years, Danishefsky et al. have successfully investigated the use of this diene in the concerted Diels-Alder reaction, including the use of enones 5 as dienophiles carried out under thermal (uncatalysed) conditions. ${ }^{16}$ They went on to find that aldehydes 6 could undergo "cyclocondensation" with the Danishefsky diene $\mathbf{4}$ in the presence of Lewis acids (Scheme 1). ${ }^{17}$

Scheme 1. The Diels-Alder reaction between Danishefsky's diene 4 and an enone 5 or an aldehyde 8.

In the early 1980s, Danishefsky et al. reported the first general cycloadditions involving simple, unactivated imines 11, catalysed by Lewis acids to form piperidine rings 12. ${ }^{18}$ This formal aza-Diels-Alder reaction was shown to work between diene $\mathbf{4}$ and $\alpha, \beta$-unsaturated imines $\mathbf{1 1}$ in the presence of zinc(II) chloride $\left(\mathrm{ZnCl}_{2}\right)^{19}$ (Equation 2). The reactions were relatively slow (1-2 days), with stoichiometric amounts of Lewis acid and a large excess (4 equivalents) of the diene being required.

## Equation 2

This methodology was later used in the synthesis of various alkaloids. ${ }^{20}$ Analogously to the use of aldehydes $\mathbf{8}$ over imines 11, it was mentioned that the mechanism went through either a concerted or Mannich-Michael process. ${ }^{21}$ However, with the lack of evidence to disprove the concerted theory, Danishefsky et al. went on to describe Lewis acid catalysed aza-Diels-Alder reactions as a "cyclocondensation reaction". ${ }^{22}$

This aza-Diels-Alder procedure was subsequently tried and tested by numerous research groups. Some groups followed the procedure without focusing on the mechanism, ${ }^{23}$ whilst others questioned the presence of a Mannich product 13, acknowledging the possibility of two conceivable mechanisms for this reaction. ${ }^{24}$ The observation of Mannich products led some to believe that this Diels-Alder process is probably a "non-synchronous concerted one". ${ }^{25}$ It was also found that instead of the Danishefsky diene, the silyl enol ether of acetyl cyclohexene $\mathbf{1 4}$ could also be used. ${ }^{26}$

13

14

Meanwhile, Raithby et al. formed bicyclic ring 19 from an electron deficient imine 16 and an electron rich diene $\mathbf{1 5}$ in the presence of a Lewis acid, during which they observed the minor Mannich product 20. They proposed that the mechanism could either be: a) concerted; b) stepwise; or c) even occur simultaneously in competition with each other (Scheme 2). ${ }^{27}$ They also suggested that varying the reaction conditions (such as solvent and temperature) makes the reaction proceed through a different process. ${ }^{28}$

19

18

20

Scheme 2. Proposed competing mechanism for the formation of products 19 and 20.

In their aza-Diels-Alder reactions, Kunz et al. used the more active $\mathrm{ZnCl}_{2}$ etherate as their Lewis acid and have argued that this process initially proceeds via a Mannich reaction followed by a cyclisation via nucleophilic intramolecular attack of the intermediate amine 23. In their examples, imines attached to a sugar acting as a chiral auxiliary 22 were reacted highly selectively with the Danishefsky diene 4 in the presence of stoichiometric amounts of $\mathrm{ZnCl}_{2}$ to give high yields of the piperidine ring 24. They showed that if the reaction was stopped after 2-12 hours with aqueous ammonium chloride solution, the Mannich compounds $\mathbf{2 3}$ could be isolated. After direct acid hydrolysis of either the reaction mixture or isolated Mannich products 23, the subsequent Michael addition occurs immediately. This is followed by elimination of methanol to give the desired unsaturated piperidine ring 24; thus proving the reaction proceeds via a Mannich-Michael mechanism (Scheme 3). ${ }^{29}$ It was also shown that the Mannich product $\mathbf{2 3}$ governs the diastereoselectivity of the Michael product 24.

Scheme 3. Kunz's procedure for piperidine ring formation using sugars as chiral auxiliaries.

Changing the R substituent of the imine did not make a difference to the reaction unless R was a large group; in such cases the yields started to diminish. ${ }^{30}$ The sugar 29 was subsequently recovered almost quantitatively after acidic cleavage of the N glycosidic bond. Through this method the tobacco alkaloid ( $S$ )-anabasin 28 was successfully synthesised in a few steps (Scheme 4). ${ }^{31}$

Scheme 4. The route taken for the formation of ( $S$ )-anabasin 28.

With the rise of resin-bound solid phase chemistry in the last decade, resin-bound aryl dialkylsilyl ethers have been used in numerous syntheses of oligosaccharides, ${ }^{32}$
glycopeptides, ${ }^{33}$ polyketides ${ }^{34}$ and prostaglandins ${ }^{35}$ to name but a few. Accordingly, Kunz et al. bound their chiral auxiliaries to dialkylsilyl resins $\mathbf{3 0}$ in order to facilitate the isolation of their subsequent piperidine ring products 32 (Scheme 5). In this case, five equivalents of $\mathrm{ZnCl}_{2}$ were used in THF at rt , the reaction taking two days. ${ }^{36}$

32
Scheme 5. Kunz et al.'s procedure using sugars bound to a resin.

Through the use of amino acids as chiral auxiliaries on the imine 33, Waldmann et al. have shown that in the presence of stoichiometric amounts of $\mathrm{ZnCl}_{2}$, the electron rich Danishefsky's diene $\mathbf{4}$ was sufficiently reactive to react with unactivated imines $\mathbf{3 3}$ to form unsaturated piperidine ring structures 36 and 37 . The chiral auxiliary was subsequently removed in a few steps. ${ }^{37}$ Depending on the imine used, poor to moderate yields were obtained with good enantioselectivity. When performing this reaction with different imines, it was noticed that the electronics of the imine substituent $\left(\mathrm{R}^{1}\right)$ did not influence the reaction outcome. Additionally, if the reaction were concerted, it would have proceeded via intermediate 34. However, by-product 38 from one of the reaction mixtures was isolated, most probably formed by nucleophilic attack of a free amino acid ester, meaning the reaction must have gone through intermediate 35. This suggested that the reaction proceeded via a MannichMichael process (Scheme 6).

36

37

38

Scheme 6. aza-Diels-Alder reaction using amino acids as chiral auxiliaries.

It was also found that chelating Lewis acids (such as $\mathrm{ZnCl}_{2}$ and $\mathrm{TiCl}_{4}$ ) afforded the same stereoisomers as non-chelating Lewis acids (such as boron and aluminium). The non-chelating Lewis acids would coordinate with the nitrogen of the imine 41 to form the conformation 42 as explained in the Felkin-Anh model ${ }^{38}$ for nucleophilic addition to carbonyl groups. According to this model, attack of the diene happens on the reface. The opposite would then be expected with chelating Lewis acids as they can also chelate to the oxygen of the carbonyl group. However, under the reaction conditions $\left(\mathrm{ZnCl}_{2}: 0{ }^{\circ} \mathrm{C}\right.$ to $-20^{\circ} \mathrm{C}$; $\mathrm{TiCl}_{4}$ : warming from $-78{ }^{\circ} \mathrm{C}$ to rt$)$ the imine double bond is isomerised as previously reported by Ojima et al., ${ }^{39}$ and hence, the diene also attacks from the $r e$-face to give the same diastereoisomer 40. Conversely, having two equivalents of $\mathrm{ZnCl}_{2}$ affords the opposite diastereoisomer 39 (Scheme 7).

41

42

Scheme 7. The different sides of attack to 41.

Weinreb et al. have shown the imine $\mathbf{4 4}$ can also cyclise with silyl enol ether $\mathbf{4 3}$ to give unsaturated piperidine rings 45 and 46 in moderate yields. ${ }^{40}$ When using catalytic amounts of $\mathrm{ZnCl}_{2}$, the syn-piperidine ring $\mathbf{4 5}$ was obtained in a ratio of 22:1 to trans46, which was a higher dr than when using $\mathrm{AlCl}_{3}$ as a Lewis acid. If needed, the synproduct 45 could be isomerised to the anti-product 46 by refluxing with $p$ - TsOH in benzene (Scheme 8).

Scheme 8. Formation of $\mathbf{4 6}$ from 43, showing improved yield from conversion of $\mathbf{4 5}$.

By screening multiple Lewis acids, Gálvez et al. further demonstrated that the Lewis acid catalysed aza-Diels-Alder reaction between 4 and 47 showed good stereoselectivity towards diastereoisomer 48, regardless of the complexing properties (Equation 3). The best selectivity was observed with stoichiometric amounts of $\mathrm{ZnI}_{2}$, followed by $\mathrm{Et}_{2} \mathrm{AlCl}$ and $\mathrm{BF}_{3} . \mathrm{Et}_{2} \mathrm{O}$, whilst the Lewis acids $\mathrm{MgBr}_{2}, \mathrm{Eu}(\mathrm{fod})_{3}, \mathrm{SnCl}_{4}$ and $\mathrm{TiCl}_{4}$ seemed to be inactive. ${ }^{41}$ Various solvents were also screened with the best results being obtained using acetonitrile followed by dichloromethane, tetrahydrofuran, diethyl ether, and lastly, toluene. This suggested that polar solvents may be important in stabilising the chelated intermediate. However, the diastereoisomers proved challenging to separate, whilst higher temperatures were needed when using less reactive imines in order to obtain acceptable yields. Mannich intermediates were also observed, suggesting the aza-Diels-Alder reaction proceeds via a Mannich-Michael process.

## Equation 3

Imines with the nitrogen attached to an aromatic ring such as compound $\mathbf{5 0}$ can undergo a Lewis acid catalysed imino-Diels-Alder reaction with an alkene $\mathbf{5 1}$ to form a ring fused piperidine 52 (Equation 4). Hence, the imine $\mathbf{5 0}$ acts as a heterodiene, which is activated by the Lewis acid. ${ }^{42}$

## Equation 4

This high-yielding reaction is completed in under an hour with the Lewis acid $\mathrm{InCl}_{3}$ present in $20 \mathrm{~mol} \%$. However, when changing the alkene 51 to a cyclohexenone 54, Perumal et al. observed that bicyclic rings 56 and 57 were formed with poor selectivity instead of $\mathbf{5 5}$. This shows that when enones 54 are present, these are activated over the imines 53 by the Lewis acid (Scheme 9). Despite the poor selectivity, it was thus serendipitously shown that the aza-Diels-Alder reaction could be performed in the presence of catalytic amounts of Lewis acid using unactivated diene equivalents, such as enone 54.

Scheme 9. Imine 53 acting as a dienophile, as opposed to a diene.

Enantioselective reactions of carbonyl compounds catalysed by chiral Lewis acids have been known for some time ${ }^{43}$ although the analogous asymmetric reactions with imines took longer to be established. ${ }^{44}$ This is partly due to the flexible $(E, Z)$ conformational structure of the imine double bond, the tendency to form enamines if an $\alpha$-acidic proton is present, as well as the fact that some imines are highly unstable and cannot be isolated. However, the main reason is that the imine nitrogen is more Lewis basic than the oxygen of the carbonyl group, thus Lewis acids tend to strongly coordinate to the nucleophilic nitrogen atom of the reactants or product, which can result in inhibition or decomposition of the chiral Lewis acid complex and low catalyst turnover. Hence, for a long time, stoichiometric amounts of Lewis acids have been needed. ${ }^{45}$

In 1998 Kobayashi et al. reported the first catalytic use of a chiral Lewis acid for the enantioselective aza-Diels-Alder reaction between an imine 11 and the Danishefsky diene 4. They used $20 \mathrm{~mol} \%$ of a chiral zirconium catalyst based on complexes with substituted 2,2 -binaphthol (BINOL), obtaining ee as high as $93 \%{ }^{46}$ From $\mathrm{Zr}(\mathrm{IV}){ }^{47}$ they subsequently went on to investigate chiral niobium Lewis acids. ${ }^{48}$ Their preferred catalyst 58 was formed in situ from ligand 59 and $\mathrm{Nb}(\mathrm{OMe})_{5}$ in the presence of N -methylimidazole (NMI).

58

59

The catalyst 58 has been shown to give highly enantioselective unsaturated piperidine rings 61 from a silyloxy diene 60 and an aromatic or aliphatic imine 11 (Equation 5).

## Equation 5

Meanwhile, Jørgensen et al. have formed piperidine ring 62 from imine 44 and the Danishefsky diene 4 with the aid of catalytic amounts ( $10 \mathrm{~mol} \%$ ) of Lewis acid. ${ }^{49}$ The catalyst was made up of a metal Lewis acidic salt and a chiral ligand to induce asymmetry. Different metal salts that were screened include $\mathrm{CuClO}_{4} 4 \mathrm{MeCN}$, $2 \mathrm{CuOTfC}_{6} \mathrm{H}_{6}, \mathrm{CuPF}_{6} \cdot 4 \mathrm{MeCN}, \mathrm{Cu}(\mathrm{OTf})_{2}, \mathrm{AgOTf}, \mathrm{AgSbF}_{6}, \mathrm{AgClO}_{4}, \mathrm{Pd}\left(\mathrm{SbF}_{6}\right)_{2}$, $\mathrm{Pd}\left(\mathrm{ClO}_{4}\right)_{2}, \mathrm{Pd}(\mathrm{OTf})_{2}, \mathrm{RuSbF}_{6}$ and $\mathrm{Zn}(\mathrm{OTf})_{2}$. The chiral ligands were either BINAP 64 or phosphino-oxazoline systems, which were individually synthesised. ${ }^{50}$ The best combination was found to be a phosphino-oxazoline-copper(I) catalyst, which afforded up to $96 \%$ yield and $87 \%$ ee. X-ray analysis suggests that the reaction proceeds via a Mannich-Michael process, evidence that was further supported by the detection of Mannich product intermediate $\mathbf{6 3}$ in some reactions (Equation 6).

## Equation 6

Within the aza-Diels-Alder reaction, isoquinolines $\mathbf{6 6}$ have been shown by Langer et al. to act as a $N$-dienophile when reacted with electron rich dienes 65 and stoichiometric amounts of Lewis acids. The reaction proceeds in a stepwise fashion, with the Lewis acid activating the imine to $\mathbf{6 8}$. Hence, nucleophilic attack by the

Brassard's type diene $\mathbf{6 5}{ }^{51}$ affords intermediate 69. Treatment of $\mathbf{6 9}$ with two equivalents of trifluoroacetic acid (TFA) aids in the tautomerisation of the carbonyl to the enol, as well as activation of the imine $\mathbf{7 0}$ for a subsequent intramolecular Michael addition. The result was a new piperidine ring 71 exhibiting an enol over a ketone (Scheme 10). The enol form is more stable by $3.3 \mathrm{kcal} \mathrm{mol}^{-1}$, which is partly due to the adjacent electron withdrawing ester group. ${ }^{52}$ This methodology has been used to form simple structural analogues of morphine.

Scheme 10. Using of Brassard's diene $\mathbf{6 5}$ for the formation of new piperidine rings.

The use of ytterbium(III) triflate ${ }^{53}$ was shown by Whiting et al. to catalyse the aza-Diels-Alder reaction asymmetrically. ${ }^{54}$ However, as with many aza-Diels-Alder examples, these reactions proved difficult to reproduce and scale up, ${ }^{55}$ which prompted the development of robust catalytic asymmetric methods. Prior to this, it was necessary to clearly understand the reaction mechanism as it was generally accepted that the aza-Diels-Alder reaction could either proceed through a concerted (either standard or inverse electron-demand Diels-Alder cycloadditions) or a stepwise
process. Indeed, after screening various dienes against electron-deficient imines in the presence of Lewis acid under different conditions, the isolated piperidine ring products gave evidence towards all three reaction pathways. However, the intermediates that were subsequently isolated showed that a stepwise additioncyclisation process derived by imine activation of the Lewis acid could explain all the reactions. ${ }^{56}$ Further investigations into this reaction to gather evidence for and against the different plausible mechanisms resulted in findings that disproved a concerted mechanism, thus suggesting that a stepwise Lewis-acid catalysed process was occurring. ${ }^{57}$

Zinc(II)-BINOL has been shown to be an efficient asymmetric catalyst in the DielsAlder reaction ${ }^{58}$ as well as the hetero-Diels-Alder reaction between dienes and aldehydes. ${ }^{59}$ Subsequently, Whiting et al. showed that zinc(II)-BINOL could also be used in the asymmetric aza-Diels-Alder reaction between electron deficient imine 72 and the electron rich Danishefsky's diene 4. ${ }^{60}$ Following on from this finding, they observed that this reaction, along with efficient asymmetric induction, was dependent upon the formation of a bidentate zinc-imine complex 74 (Scheme 11). ${ }^{61}$

Scheme 11. Binding of zinc(II)-BINOL to imine 72.

As expected, the cycloaddition proceeds via a two-step process. The imine must be suitably activated for the initial Mannich-like step, which means that, when possible, the $\operatorname{zinc}($ II $)$-BINOL forms a bidentate ligand with the imine (Scheme 11 and Scheme 12) (aromatic imines would form monodentate ligands).

Scheme 12. Binding of $\mathrm{Zn}(\mathrm{II})$-BINOL to imine 75.

After formation of the bidentate ligand $\mathbf{8 0}$, addition of the diene $\mathbf{4}$ to the imine $\mathbf{8 0}$ can take place. Ring closure of $\mathbf{8 3}$ is a slow process that can be accelerated with an acidic work up. As $S$-BINOL is used in this case, the $S$-enantiomer product $\mathbf{8 4}$ is obtained. However, a competing reaction of the activated iminium ion $\mathbf{8 2}$ with diene $\mathbf{4}$ forms the racemic product $\mathbf{8 4}$ through intermediate $\mathbf{8 5}$ (Scheme 13).

Scheme 13. Piperidine ring formation between Danishefsky's diene 4 and the imineLewis acid complex 80.

For these reactions, there seem to be two competing effects. Firstly, the presence of a catalytic equilibrium between monomer and dimer complexes in solution is important, and secondly, low catalyst loadings seems to be less effective due to the likelihood of competing silicon transfer effects.

Iodine has been shown by Yao et al. to be effective as a Lewis acidic catalyst in the aza-Diels-Alder reaction. ${ }^{62}$ These iodine-catalysed reactions can either be performed neat or at high concentrations. Additionally, as iodine is a strong Lewis acid, the reaction can be performed without the need of an electron rich diene such as Danishefsky's diene 4. The best results were also obtained with the use of 0.5 equivalents of iodine. Hence, it was shown that aldehydes 8, amines 86 and cyclic enone 87 react together in the presence of iodine to form fused piperidine rings 88 in $55-95 \%$ yield; the best yields were obtained when $\mathrm{R}^{1}$ was electron withdrawing (Equation 7).

## Equation 7

Similar results were observed when using cyclohexenone $\mathbf{5 4}$ as the diene source to form bicyclic compounds 93 and 94 . However, when using the 5 -membered ring acetylcyclopentene $\mathbf{9 1}$ as opposed to the six-membered cyclohexenone 54, the yields obtained for 92 were drastically diminished to less than $10 \%$ (Scheme 14). This may suggest that the spatial alignment of the enone is important in order for the aza-DielsAlder reaction to proceed effectively.

Scheme 14. Comparing acetylcyclopentene 91 and cyclohexenone 54 as the enone within the aza-Diels-Alder reaction.

Understanding that the aza-Diels-Alder reaction proceeds via a Mannich-Michael process, Hoveyda et al. optimised their silver catalysed Mannich reactions prior to performing the aza-Diels-Alder reaction between imines and the Danishefsky diene 4. ${ }^{63}$ These silver catalysed reactions required an additive ( $i$ - PrOH ) and performed well in an atmosphere of air using THF as solvent. This was subsequently optimised into a three-component, one-pot synthesis using $5 \mathrm{~mol} \%$ of the silver Lewis acid and 5 $\mathrm{mol} \%$ of the chiral ligand 96 to give the desired piperidine ring 97 in good yield and high diastereo- and enantio-selectivity (Equation 8).

## Equation 8

The Lewis acid catalysed aza-Diels-Alder reaction has also been shown to be useful in the formation of indolizidines 103, an important biologically active class of alkaloids found in numerous natural products. ${ }^{64} \mathrm{An}$ imine such as $\mathbf{1 0 1}$ derived from
allylsilane amine ${ }^{65}$ has been shown by Furman et al. to be necessary to react smoothly with Danishefsky's diene 4 in the presence of $10 \mathrm{~mol} \% \mathrm{Yb}(\mathrm{OTf})_{3}$ in order to form the piperidine ring 102 in good yields. ${ }^{66}$ Nonetheless, it was subsequently found that the best chiral Lewis acid at their disposal was the chiral boron complex 100, which was used in stoichiometric amounts. This boron complex was formed in situ from 98 and 99 (Equation 9). ${ }^{67}$

## Equation 9

The key step to form the indolizidine $\mathbf{1 0 3}$ involves a cyclocondensation reaction in the presence of tetrabutylammonium triphenyldifluorosilicate (TBAT). ${ }^{68}$ This reaction is stereospecific, the stereochemistry subsequently proved through circular dichroism spectroscopy (Scheme 15); ${ }^{67}$ a technique first used on such systems by Whiting et $a l .{ }^{57}$

Scheme 15. A route to indolizidines via the aza-Diels-Alder reaction.

The use of silicon Lewis acids within the aza-Diels-Alder reaction between hydrazone 105 and Danishefsky's diene 4 has been investigated by Leighton et al.. Good yields and high enantioselectivities (up to $85 \%$ and $92 \%$ respectively) were generally observed with these reactions. ${ }^{69}$ There seems to be a strong solvent effect when using silicon Lewis acids, shown by the observation that using dichloromethane instead of toluene gives the opposite enantiomer of the aza-Diels-Alder product (Scheme 16).

Scheme 16. Silicon Lewis acids and their use within the aza-Diels-Alder reaction.

It is also mechanistically interesting to note that two silicon catalysts were synthesised and tested: $\mathbf{1 0 3}$ and 104. Catalyst $\mathbf{1 0 3}$ had previously been proven to be effective for a variety of transformations of acylhydrazones. ${ }^{70}$ However, it proved to be ineffective in the Mannich reaction. ${ }^{71}$ Consequently, when catalyst $\mathbf{1 0 3}$ was used as the Lewis acid in the aza-Diels-Alder reaction, the reaction did not proceed. Instead, catalyst 104 had been shown to perform well in enantioselective Mannich reactions ${ }^{71}$ and when subsequently used within the aza-Diels-Alder reaction, the reaction proceeded efficiently. These findings suggest that the aza-Diels-Alder reaction could be proceeding through a Mannich reaction, thus adding evidence that the aza-Diels-Alder reaction goes through a two-step process via a Mannich-Michael pathway as opposed to being concerted. Armed with these findings, Leighton et al. went on to synthesise casopitant 111, a neurokin 1 receptor antagonist, ${ }^{72}$ after forming the core piperidine ring 108 via an aza-Diels-Alder reaction using their silicon Lewis acid 104 (Scheme 17).

Scheme 17. Synthesis of casopitant 111 from the aza-Diels-Alder product 108.

If one wants to bring down the reaction time for the aza-Diels-Alder reaction, then activation by microwave irradiation is a viable option as demonstrated by Török et al. when using silicotungstic acids as catalysts. ${ }^{73}$ After screening different heteropolyacids ${ }^{74}$ they were able to show that their one-pot, three-component system forms the aza-Diels-Alder product 114 in good yields and diastereoselectivities within 10 min when performed in a microwave at $100{ }^{\circ} \mathrm{C}$, using $\mathrm{H}_{4}\left[\mathrm{SiW}_{12} \mathrm{O}_{40}\right]$ as the catalyst (Equation 10).

Equation 10

### 1.3 Asymmetric Construction using Brønsted Acids

The use of Brønsted acids in the aza-Diels-Alder process can be simply explained in the context of the reaction between a cyclic enone 54 and an imine 11, whereby the Brønsted acid activates both these reagents. As seen in Scheme 18, under acidic conditions, the ketone tautomerises to enol 115. This then undergoes a Mannich reaction with the protonated imine 116, followed by an intramolecular aza-Michael addition to give the endo-118 and exo-119 bicyclic products and regenerating the acid catalyst at the same time.

Scheme 18. General procedure for the Brønsted acid catalysed aza-Diels-Alder reaction.

The success of this reaction depends on the proton-donating capacity of the catalyst (acidity) and on the experimental conditions, particularly the solvent. Piermatti et al. have been able to perform such reactions in water using $\alpha$-zirconium hydrogen phosphate $\left(\alpha-\mathrm{Zr}\left(\mathrm{HPO}_{4}\right)_{2} \mathrm{H}_{2} \mathrm{O}\right)$ as the Brønsted acid to give yields of $70-90 \%$, although with hardly any selectivity between the endo-118 and exo-119 products (50:50 $55: 45) .{ }^{75}$

Prior to this finding, Akiyama et al. made significant progress in this field of green chemistry by demonstrating that the three-component, one-pot aza-Diels-Alder reaction between an aldehyde 8, amine $\mathbf{1 2 0}$ and Danishefsky's diene $\mathbf{4}$ can be performed solely in water, using sodium dodecyl sulphate (SDS) as a surfactant. ${ }^{76}$

This reaction proceeds giving the racemic product 121 in good yield, using fluoroboric acid ( $10 \mathrm{~mol} \%$ ) as a catalyst (Equation 11).

Equation 11

Following on from this work, Kobayashi et al. carried on experimenting with the aza-Diels-Alder reaction in water. In one set of reactions, amines 86, aldehydes 8 and the Danishefsky diene 4 were reacted together in the presence of catalytic AgOTf at room temperature for two-three hours (Equation 12). ${ }^{77}$ The use of Danishefsky's diene 4 in this reaction using water as a solvent was believed to be beneficial because it was thought that Danishefsky's diene $\mathbf{4}$ probably hydrolyses slower under these heterogeneous reaction conditions, thus preventing formation of side products. However, only the racemic product was obtained. It was subsequently found that the slow addition of the diene 4 over a period of an hour dramatically helped to improve yields. Yields were subsequently increased by up to $20 \%$ through the use of non-ionic surfactants such as 'Triton X-100'. It was thought that the role of this surfactant was to help the formation of the imine, as no improvements were observed in the twocomponent reaction. Higher equivalents of diene 4 also gave higher yields of up to 90\%.

## Equation 12

Through the use of $\alpha, \beta$-unsaturated esters over ketones, the Mannich reaction can be investigated and optimised independently in order to give a greater understanding of
the Mannich-Michael ring forming process. Hence, Mannich reactions between imines $\mathbf{1 2 2}$ and acyclic silyl dienolate $\mathbf{1 2 3}$ using catalytic amounts of Brønsted acids have been optimised by Schneider et al.. ${ }^{78}$ This they achieved with $5 \mathrm{~mol} \%$ of their BINOL-based phosphoric acid catalyst 124 in a solvent mixture at $-50^{\circ} \mathrm{C}$. The low temperature was necessary in order to improve enantioselectivity; a lower temperature would have frozen the solvent mixture (Equation 13).

Equation 13

After optimisation of their chiral Brønsted acid, Schneider et al. found that higher enantioselectivities were observed when the R group on the ester $\mathbf{1 2 5}$ was small. When using aromatic protecting groups on the imine, having electron-donating groups on the para-position afforded high enantioselectivities, whereas the reaction became non-selective when this group was on the ortho-position. The main effect that the Rsubstituent of the imine had on this reaction was to slow the reaction down. Hence, the reaction times ranged from twelve hours to a week, with most reactions going to completion within two days; increasing the low catalytic concentration would undoubtedly speed up the reaction. When using $\gamma$-substituted silyl dienolates, it was found that an $E$-geometry 126 would mainly afford the anti-product $\mathbf{1 2 7}$ (Equation 14), whilst the $Z$-geometry $\mathbf{1 2 8}$ would mainly afford the syn-product $\mathbf{1 2 9}$, although with lower yield and poor diastereoselectivity (Equation 15).

Equation 14

## Equation 15

Mechanistic investigations were carried out to explain the role of the solvent system (equal amounts of $t$ - $\mathrm{BuOH}, 2$-methyl-2-butanol and THF with one equivalence of water) as well as the reaction mechanism. Hence, the alcohol component was shown to be important for the rate of the reaction, with the water content further accelerating the reaction. 2-Methyl-2-butanol was needed in order to decrease the allowed reaction temperature, whilst THF had a beneficial effect on the selectivity of the reaction. This solvent system is thought to trap the cationic silicon species as silanol and regenerate the chiral Brønsted acid catalyst through protonation. Thus, in the proposed catalytic cycle, the Brønsted acid $\mathbf{1 2 4}$ protonates the imine $\mathbf{1 2 2}$ whilst shielding the Re-face, making the protonated imine $\mathbf{1 3 0}$ sufficiently activated to undergo the Mannich reaction with the silyl dienolate $\mathbf{1 2 3}$ from the opposite side. The intermediate $\mathbf{1 3 2}$ was subsequently hydrolysed to give the Mannich product 125 (Scheme 19). This reaction was also shown to proceed well in a one-pot, three-component manner by forming the imine in situ.

Scheme 19. Proposed catalytic cycle for the formation of $\mathbf{1 2 5}$ from $\mathbf{1 2 2}$ and 123.

The first Brønsted acid catalysed aza-Diels-Alder reaction using unactivated cyclohexenone 54 as opposed to the activated Danishefsky diene $\mathbf{4}$ was reported by Gong et al. through their use of chiral phosphoric acids. ${ }^{79}$ The reaction relies on the acid enolising the carbonyl group of $\mathbf{5 4}$ in order to generate an electron-rich diene $\mathbf{1 1 5}$ in-situ, and thus, attack the protonated imine 116 in order to undergo a Mannich reaction, followed by an intramolecular Michael addition (Scheme 20).

Scheme 20. The route to bicyclic piperidine rings 118 and 119 from a cyclic enone 54.

The reaction shown in Scheme 20 took six days with two equivalents of enone $\mathbf{5 4}$ and $5 \mathrm{~mol} \%$ of optimised chiral phosphoric acids $\mathbf{1 3 5}$ at room temperature. It was found that lower temperatures gave higher enantioselectivites; nevertheless the overall yields were notably decreased. The use of different solvents only affected the yields, with non-polar solvents such as toluene affording the highest yields. Dichloromethane follows this, with polar solvents such as THF exhibiting the lowest yields. Similar results in terms of yields and stereoselectivites were observed when the aromatic electronics of the nitrogen-protecting group were changed. Finally, the optimised reaction was effectively performed in a three-component one-pot fashion (Equation 16).

## Equation 16

A double Brønsted acid catalysed reaction using the chiral BINOL-phosphoric acid 138 ( $10 \mathrm{~mol} \%$ ) and acetic acid as an achiral acid ( $20 \mathrm{~mol} \%$ ) was successfully performed to form bicyclic piperidine rings $\mathbf{1 4 0}$ from imines $\mathbf{1 1}$ and cyclohexenone 54. Rueping et al. ${ }^{80}$ have shown that both catalytic acids need to be of different strengths, with the achiral catalyst having a much higher $\mathrm{p} K_{\mathrm{a}}$ so that it would not be able to compete with the chiral acid 138 in activating the imine 11, which would have resulted in reduced enantioselectivity. Hence, the chiral acid $\mathbf{1 3 8}$ activates the imine 11 generating the more electrophilic 116, whilst the achiral acid tautomerises the ketone 54 into a nucleophilic enol 115. Consequently, the imine and enone are able to
cyclise via a Mannich-Michael process (Scheme 21) to give 140 in moderate yields and high enantioselectivity.

Scheme 21. Proposed catalytic cycle for piperidine ring formation using two acid catalysts.

Work done by Feng et al. have also shown that ytterbium is the Lewis acid of choice when performing the aza-Diels-Alder reaction; scandium, samarium, yttrium and lanthanum all gave lower yields than ytterbium. ${ }^{81}$ Furthermore, Brassard's diene 65 was used instead of the Danishefsky diene 4; the use of Brassard's diene $\mathbf{6 5}$ using chiral Brønsted acid catalysts had only been mentioned once before within the literature. ${ }^{82}$ The double substitution at the terminus of Brassard's diene $\mathbf{6 5}$ makes this diene less enantioselective, which can explain the previous low usage of this diene. ${ }^{83}$ It was observed that after reacting Brassard's diene 65 with an imine 141 in the presence of the Brønsted acid, the Mannich product 143 was obtained. 143 was subsequently cyclised by heating it with benzoic acid to form the piperidine ring 144, thus suggesting that the overall mechanism of the cycloaddition is stepwise as opposed to being concerted (Scheme 22). The use of ligand complexes was shown to greatly increase the enantioselectivities (up to $81 \%$ ee), with yields of up to $58 \%$ being obtained. Feng et al. have also shown that with their aza-Diels-Alder reactions,
higher yields are also obtained when the reaction is performed in solvent-free conditions and that this also applies to the one-pot, three-component reactions. ${ }^{84}$ Hence, these findings suggest that it may be best to use the minimum amount of solvent within the aza-Diels-Alder reactions.

Scheme 22. The use of chiral Yb complexes within the aza-Diels-Alder reaction.

If one wants to perform the aza-Diels-Alder reaction in water, Vaccaro et al. have shown that this is possible when using zirconium hydrogen phosphate alkyl and/or aryl phosphonates $\left[\mathrm{Zr}\left(\mathrm{PO}_{3} \mathrm{OH}\right)_{2-(\mathrm{x}+\mathrm{y})}\left(\mathrm{PO}_{3} \mathrm{R}\right)_{\mathrm{x}}\left(\mathrm{PO}_{3} \mathrm{R}^{\prime}\right)_{\mathrm{y}}\right]$ as heterogeneous Brønsted acids. ${ }^{85}$ They report that a high concentration of hydrophobic groups ( $\mathrm{Me}, \mathrm{Ph}$ and Pr ) on their solid catalyst favours reagent diffusion towards the acidic sites in order to aid proton transfer to the reagents. As a result, no additives are needed in their system and both the Mannich ( $\mathbf{1 4 9}$ and $\mathbf{1 5 0}$ ) and aza-Diels-Alder ( $\mathbf{1 4 7}$ and $\mathbf{1 4 8}$ ) products were obtained in good conversion (Scheme 23).

Scheme 23. An aza-Diels-Alder reaction performed in water, where $\mathrm{BH}=$ $\mathrm{Zr}\left(\mathrm{PO}_{3} \mathrm{OH}\right)_{0.37}\left(\mathrm{PO}_{3} \mathrm{Me}\right)_{0.65}\left(\mathrm{PO}_{3} \mathrm{Ph}\right)_{0.98}-0.7 \mathrm{H}_{2} \mathrm{O}$.

### 1.4 Asymmetric Construction using Organocatalysis

As it is generally accepted that the aza-Diels-Alder reaction proceeds via a MannichMichael process, understanding each of these processes is highly important. Asymmetric Mannich reactions can afford high diastereo- and enantio-selectivities with the use of pyrrolidine derived catalysts. ${ }^{86}$ It has been widely shown that having an ( $R$ )-carboxylic acid group on the 2-position of pyrrolidine 152 (i.e. L-proline) makes the Mannich reaction syn-selective 154 (Scheme 24). ${ }^{87}$

Scheme 24. syn-Selectivity of the L-proline 152 catalysed Mannich reaction between an imine and a ketone or an aldehyde compound.

Conversely, Tanaka et al. have shown that having the ( $S$ )-carboxylic acid group on the three-position of pyrrolidine $\mathbf{1 5 4}$ makes this an anti-Mannich catalyst, thus giving the anti-product 160 (Scheme 25).

Scheme 25. anti-Selectivity of the catalyst 156 between imines and ketones.

Condensation of the catalyst with the ketone would afford an enamine interconverting between conformations 157 and 158. However, only conformation 158 will react further with the imine 155 via a preferred transition state 159 whereby the acid and the nitrogen of the imine are H -bonding with each other. Hence, stereoselective Mannich product $\mathbf{1 6 0}$ is formed.

When exploring the L-proline catalysed Mannich reaction between methyl-ketones 162 and imines 161, Ohsawa et al. found that at room temperature with $5 \mathrm{~mol} \%$ of catalyst, high yields (up to $99 \%$ ) of Mannich product 163 were obtained after three days when 50 equivalents of water were present in the reaction mixture; under dry conditions almost no stereoselectivity was observed, whilst too much water drastically decreased the reaction rate (Equation 17). ${ }^{88}$

## Equation 17

Lower temperatures also greatly decreased the rate of reaction. However, the stereoselectivity was improved. When the same reaction was performed using methyl vinyl ketone 164, dry conditions were necessary in order to sufficiently increase the rate of reaction, with $50 \mathrm{~mol} \%$ of catalyst $\mathbf{1 5 2}$ being used. Even then, the reaction took a week to proceed (Equation 18). This work was published in 2003, and was one of the first to show that L-proline $\mathbf{1 5 2}$ can be used in the aza-Diels-Alder reaction.

## Equation 18

The unprotected $\mathbf{1 6 5}$ is a precursor for the synthesis of indole alkaloids such as deserpidine ${ }^{89}$ and yohimbine. ${ }^{90}$ In 2006, Ohsawa et al. reported their findings (to access one of these alkaloids) using different enones catalysed with $30 \mathrm{~mol} \%$ of L proline $\mathbf{1 5 2}$. ${ }^{91}$ Despite the reaction taking a week to go through to completion, using 30 equivalents of enone 166, high yields and enantio- and diastereo-selectivities were obtained. With three further steps, the alkaloid ent-dihydrocorynantheol 168 was synthesised asymmetrically (Scheme 26). Seeing as this reaction was proceeding in the same manner as when simple methyl ketones 162 were used as a reagent over enones, it was thought the reaction was proceeding via a Mannich-Michael process. Hence, the large excess of enone 166 that was needed would suggest that the initial Mannich reaction was the rate-determining step.

Scheme 26. The aza-Diels-Alder reaction for the formation of the alkaloid entdihydrocorynantheol 168.

Córdova et al. first mentioned the use of cyclohexenones $\mathbf{1 6 9}$ within the aza-DielsAlder reaction with pyrrolidine derived organocatalysts in 2005, in order to produce
enantioselective bicyclic piperidine rings $\mathbf{1 7 1}$ in moderate yields. This reaction was performed in a three-component one-pot manner using enones 169, formaldehyde $\mathbf{1 7 0}$ and $p$-anisidine $\mathbf{1 2 0}$ (Equation 19). ${ }^{9}$

Equation 19

Different solvents were used, and it was found that after 24 hours at $50^{\circ} \mathrm{C}$, DMSO gave better yields ( $52 \%$ ), followed by DMF ( $35 \%$ ), NMP ( $10 \%$ ) and toluene ( $<5 \%$ ). High ee of $99 \%$ was obtained from L-proline 152 and the Ley catalyst 172, with slightly lower ee ( $94 \%$ ) obtained with the amide catalyst $\mathbf{1 7 3}$. When performing the reaction at room temperature, a lower yield of $30 \%$ was obtained when using catalyst 152. However, at room temperature, catalyst 172 gave a slightly higher yield of $61 \%$. After deciding to use the cheaper L-proline $\mathbf{1 5 2}$ catalyst, the reaction was performed using various enones to give a range of bicyclic piperidines in similar ee and yield. In one example, when using enone 174, only the $\alpha, \beta$-unsaturated Mannich product 175 was obtained.

172

173

174

175

Formation of $\mathbf{1 7 5}$ was used as evidence to propose that the aza-Diels-Alder reaction was proceeding via a Mannich-Michael, as opposed to a concerted process; presumably the methyl group on the enone was blocking the amine's access to the Michael receptor. Various aromatic amines were also screened and it was found that neutral aromatic rings gave lower yields than the electron donating PMP ring, with $p$ halogenated aromatics giving the lowest yields. Furthermore, trace amounts of Mannich adduct were also observed when using the $p$-halogenated aromatic amines,
which is further proof that this reaction proceeds via a Mannich-Michael process. Hence, a chiral enamine $\mathbf{1 7 7}$ is first formed; with the in-situ generated imine $\mathbf{1 7 8}$ attacking it from the Si-face via transition state $\mathbf{1 8 2}$ (Scheme 27). The trace amounts of $p$-halogenated aromatic amines observed could be attributed to the lower nucleophilicity of the secondary amine intermediate in the Michael step.

Scheme 27. Proposed catalytic cycle for the formation of bicyclic piperidine rings via the aza-Diels-Alder reaction.

When using L-proline $\mathbf{1 5 2}$ as the organocatalyst, the syn-selectivity of the Mannich reaction can be used to form cis-2,6-diarylpiperidin-4-ones $\mathbf{1 8 5}$ from their corresponding enones $\mathbf{1 8 3}$ and imines $\mathbf{1 8 4} .^{92}$ However, the advantages of using Lproline are limited by the fact that four equivalents of the enone were needed to produce a moderate yield, as well as the limited number of solvents this reaction was effective in. Despite this, high diastereoselectivity was observed with these reactions,
although no enantioselectivity was obtained when the R substituents on the ring were different (Scheme 28).

Scheme 28. Different routes for the formation of the deprotected piperidine ring 187.

It is also interesting to note that the reaction only seems to proceed efficiently with an aliphatic protecting group on the nitrogen of imine 184. Low conversions were obtained when this protecting group was aromatic, meaning more traditional nitrogen protecting groups such as $p$-methoxyphenyl could not be used. Aznar et al. have shown that a convenient aliphatic protecting group in such cases would be an allyl group as this group could easily be removed after the cycloaddition using Grubbs' catalyst, the methodology of which was serendipitously discovered in Madrid by Alcaide et al. ${ }^{93}$ In their quest for synthesising bioactive $\beta$-lactams 188, Alcaide et al. found that in some cases, isomerisation of the internal double bond in a $N$-allyl amide 189 was favoured over ring-closing metathesis (Scheme 29).

Scheme 29. An observed ring-closing anomaly with Grubbs' catalyst.

Consequently Alcaide et al. looked into this phenomenon using different $N$-allyl amines and found that Grubbs' catalyst efficiently catalysed the deprotection of tertiary amines 191. Mechanistic studies showed that the reaction proceeds via a ruthenium-catalysed isomerisation to a more stable olefin 194, followed by hydrolysis to afford the amine 195 (Scheme 30).

Scheme 30. Deprotection of allylic tertiary amines using Grubbs' catalyst.

Regarding the organocatalyst, Aznar et al. also screened the aza-Diels-Alder reaction against the pyrrolidine derived catalysts 196 and $197 .{ }^{94}$ Both of these catalysts were ineffective by themselves in the reaction between enone 183 and imine 184. However, in the presence of $20 \mathrm{~mol} \%$ of $p$-toluenesulfonic acid, piperidine ring 185 was formed in $58 \%$ and $61 \%$ yields respectively. These results suggested that some acidic source is required to promote formation and equilibration of the initial iminium ion to the reactive enamine. In the case of L-proline 152, the acid was incorporated into the organocatalyst. Hence, no extra acidic source was needed to promote the aza-DielsAlder reaction, unlike with the pyrrolidines 196 and 197.

152

196

197

When looking into organocatalysed methods for accessing nitrogen-containing bicyclic rings 119 in a highly enantioselective and diastereoselective manner, Carter et al. ${ }^{95}$ suggested that the initial Mannich reaction proceeds via the transition state put forward by Houk (Scheme 31). ${ }^{96}$ In this system, the syn-zwitterionic product 200
governs the subsequent aza-Michael cycloaddition in order to form the enamine 203. This mechanism would explain the strong exo-preference observed in these reactions. However, higher catalyst loadings of $\mathbf{1 9 8}$ ( $30 \mathrm{~mol} \%$ ) compared to standard aldol ${ }^{97}$ and Mannich reactions ${ }^{98}$ were necessary because cleavage of the enamine 203 in this example was slow due to increased steric congestion.

Scheme 31. The aza-Diels-Alder reaction using the organocatalyst 198.

Franzén et al. have found proline-derived organocatalysts $\mathbf{2 0 5}$ to be useful in the direct synthesis of quinolizidine skeletons 211-214, with the formation of three new stereocentres (Scheme 32). ${ }^{99}$

Scheme 32. The use of the aza-Diels-Alder reaction for the formation of fusedpiperidine ring compounds.

Thus, catalyst 205 attacks the enone 204 to form the chiral iminium intermediate 206. This shields the $R e$-face and hence, conjugate addition of the amide would happen on the Si-face. After the addition of 207, the compound $\mathbf{2 0 8}$ cyclises spontaneously to form the hemiacetal 209. This compound was observed to be in the thermodynamically stable $2 R, 3 S$-trans-configuration due to epimerisation of the stereochemically labile stereocentre at C3. In the presence of catalytic amounts of acid, the hemiacetal 209 then converted into the acyliminium ion 210, which could then undergo aromatic substitution to give the quinolizidine products 211-214. This reaction is noted to be under kinetic control, with high to excellent enantioselectivity and moderate diastereoselectivity. This was thought to be due to less steric hindrance from the equatorial $\alpha$-proton in the transition state 215 (Scheme 33).

Scheme 33. The transition states for the kinetic 216 and thermodynamic 218 products.

Recently, a one-pot three-component tandem reaction has been shown by Chen al. to form piperidine containing spirocyclic oxindoles 224. ${ }^{100}$ They had previously found that with the aid of a chiral organocatalyst 205, achiral bifunctional compound 221 could be formed from the asymmetric Michael addition of aliphatic aldehydes 219 to electron-deficient olefinic oxindoles 220. They subsequently found that $N$-Boc-imines 222 could be used as electrophiles in the reaction with intermediate 221, with tetramethylguanidine (TMG) catalysing this highly diastereoselective Mannich reaction to afford the hemiaminal 223 in the same pot. This hemiaminal 223 was directly dehydroxylated to afford the piperidine derivatives $\mathbf{2 2 4}$ in moderate yields with high enantioselectivities (Scheme 34). Thus, by altering the aromatic groups, spirocyclic oxindoles such as $\mathbf{2 2 5}$ may be synthesised; $\mathbf{2 2 5}$ is a potent non-peptide MDM2 inhibitor, which may be useful as an anticancer agent. ${ }^{101}$

Scheme 34. The use of the aza-Diels-Alder reaction to form spirocyclic piperidine ring compounds.

Interestingly, Schneider et al. have recently shown that Mannich-Michael reactions can be performed from imines $\mathbf{1 5 5}$ and an aldehyde tethered to an enone 226 in the presence of catalytic amounts of L-proline 152 ( $20 \mathrm{~mol} \%$ ); the tether forming part of the synthesised piperidine ring 227. ${ }^{102}$ The enone group in 226 has a chiral auxiliary attached to it; hence, it contains no acidic $\alpha$-protons. Thus, the organocatalyst 152 solely formed an enamine with the aldehyde group in 226, through which a Mannich reaction occurred with the imine $\mathbf{1 5 5}$. The Mannich adduct subsequently underwent an intramolecular aza-Michael reaction with the enone, thus forming the highly substituted piperidine ring 227 in moderate yields and good stereocontrol after subsequent aldehyde reduction (Equation 20). Small amounts ( $<5 \%$ ) of the uncyclised Mannich product were also observed. Reaction time was 24 hours at $-20^{\circ} \mathrm{C}$ and it was found that if the imine was not reactive enough, no reaction was observed as the initial Mannich reaction did not precede. The reaction was also performed using Dproline as the catalyst, which afforded the piperidine ring with opposite configuration at the two- and three-positions. This demonstrated that the initial Mannich step was catalyst-controlled, whereas the subsequent Michael addition was substrate controlled, hence the need for a chiral auxiliary in this case.

## Equation 20

The use of enzymes to catalyse organic transformations ${ }^{103}$ is becoming more prevalent within the chemistry community, ${ }^{104}$ with an aza-Diels-Alder example recently being published by Guan et al.. ${ }^{105}$ In their system, they found that Hen Egg White Lysozyme (HEWL) efficiently promotes the one-pot, three-component reaction between an amine 113, aldehyde $\mathbf{1 1 2}$ and 2-cyclohexen-1-one $\mathbf{5 4}$ in order to form the aza-Diels-Alder product 228 in good yield and stereoselectivity (Equation 21).

Yield: up to 98\% endo / exo: up to 90:10

## Equation 21

### 1.5 Other aza-Diels-Alder reactions using imines as the dienophile

To overcome the need to protect the amine in the aza-Diels-Alder reaction, Edwards et al. have shown that piperidine rings can be formed in a one-pot, three-component fashion when using ammonia as the nitrogen source. However, low yields of 20-35\% were generally observed. ${ }^{106}$ This methodology was subsequently used in the synthesis of frog alkaloids such as the biologically active piperidine 241D (235). ${ }^{107}$ Hence, reaction of an enone 230 and aldehyde 232 with $\mathrm{NH}_{4} \mathrm{OAc}$ (231) in methanol predominantly afforded the cis-isomer of the piperidine ring 234 (80:1, cis to trans) in $25 \%$ yield. Subsequent reduction of the carbonyl group using sodium borohydride gave cis,cis-4-hydroxy-2-methyl-6-nonylpiperidine (235) as the major product (Scheme 35). Edwards et al. noted that the one-step ring-closing reaction most probably goes via Mannich and Michael condensations.

Scheme 35. Synthesis of the frog alkaloid 235 via an aza-Diels-Alder reaction.

Ding et al. have shown that $N$-aryl imines undergo an acid-free aza-Diels-Alder reaction with Danishefsky's diene 4 in MeOH , where it was suggested that the reaction goes through a Mannich-type pathway due to the regioselectivity of the reaction and the observance of the Mannich product in the crude mixture. ${ }^{108}$ Following on from this work with an aim of synthesising imines through an alternative method, Yan et al. have shown a method to perform metal-free aerobic oxidative coupling of amines to form imines by refluxing aerated suspensions of water and benzylamines 236. After extracting the imines from the aqueous solvent, followed by concentration in vacuo, the imines were mixed with a methanol solution of Danishefsky's diene $\mathbf{4}$ to form the aza-Diels-Alder products 237 in moderate yields (Equation 22). ${ }^{109}$

## Equation 22

The use of chiral ionic liquids within the aza-Diels-Alder reaction has been explored by Vo-Thanh et al..$^{110}$ Interestingly, in this case the ionic liquid $\mathbf{2 3 9}$ was also being used as the solvent, which removed the need for acids or any other catalyst within the reaction mixture. ${ }^{111}$ It was noted that these chiral ionic liquids were recycled, with their efficiency being preserved, thus making this a green alternative to the traditional Lewis acid mediated aza-Diels-Alder reaction between Danishefsky's diene 4 and imines 238. It was thought that the reaction proceeds though intermediate 241, with yields of up to $66 \%$ and de of $60 \%$ of $\mathbf{2 4 0}$ being obtained at room temperature. Higher yields were obtained at lower temperatures due to a reduction in decomposition of Danishefsky's diene 4. However, in such cases only the racemic product was obtained. Thus in order to reduce decomposition of Danishefsky's diene 4 at room temperature, the diene $\mathbf{4}$ was added in three phases at equal intervals, consequently improving the yield by $20 \%$ compared to when the diene 4 was added all at once (Scheme 36).

Cinchona-derived catalysts ${ }^{112}$ have been developed and used since the late 1970s. Using this methodology, Park et al. have recently shown that these cinchona-derived ammonium catalysts $\mathbf{2 4 2}$ can also be prepared and applied to the aza-Diels-Alder reaction between an imine 11 and Danishefsky's diene 4 in order to form different dihydropyridones $\mathbf{1 2} .^{113}$ After optimisation of the catalyst 242, they were able to achieve the racemic product 12 in good yield (Equation 23).

Scheme 36. The use of Ionic liquid 239 within the aza-Diels-Alder reaction, showing its possible interaction with the substrates 238 and 4.

Equation 23

Subsequently, Park et al. tried to increase their substrate scope by reacting cyclic arylimines 243 with Danishefsky's diene $\mathbf{4}$ in the presence of their catalysts 242. In doing so, they were able to synthesise polycyclic-dihydropyridones 244 and 247, which are essentially the skeletons for the medical drug tetrabenazine $\mathbf{2 4 5}^{114}$ (used to treat chorea associated with Huntington's disease) and the alkaloid tangutorine $\mathbf{2 4 8}^{115}$ respectively (Scheme 37). However, lower yields of $50-54 \%$ were obtained for these
cyclisations, presumably because the conjugation between the imine and the aromatic rings significantly lowers the reactivity of the system. Despite their moderate yields, this was the first time that the synthesis of polycyclic-dihydropyridones via an aza-Diels-Alder pathway had been reported.

Scheme 37. The use of cyclic arylimines within the aza-Diels-Alder reaction.

As can be seen in the literature, the evidence suggests that when using electron rich dienes within the aza-Diels-Alder reaction, the process can be thought of as going through a Mannich-Michael reaction. ${ }^{116}$ Using this Mannich-Michael principle, Raabe et al. have shown an example to form five-membered ring $N$-heterocycles $\mathbf{2 5 3}$ instead of 6 -membered ones. ${ }^{117}$ They performed this by reacting imines 249 with $\gamma$-malonatesubstituted $\alpha, \beta$-unsaturated esters 250 in the presence of bifunctional thioureas as catalysts. In their studies, they found that the Mannich product $\mathbf{2 5 2}$ was only formed when $\mathrm{R}=\mathrm{H}$. In order to make the intramolecular Michael addition proceed with the generated secondary amine, they found that they needed to make the Michael acceptor more electrophilic, which they achieved by adding an additional ester function to the double bond. Hence, when $\mathrm{R}=\mathrm{CO}_{2} \mathrm{Me}$, they were able to obtain the cyclised product 253 in good yield. This example shows the importance of the electronics of the system in order to make the Mannich-Michael reaction proceed in the way one wishes.

Scheme 38. A Mannich-Michael cycloaddition to form five-membered $N$ heterocycles 253.

### 1.6 Other aza-Diels-Alder reactions using azadienes

When the nitrogen component is located within the diene, different piperidine ring derivatives are obviously formed compared to when the nitrogen is located within the dienophile, ${ }^{118}$ and below are a few of the more recent examples found within the literature. For example, Palacios et al. have shown that 1 -azadienes (i.e. $\alpha, \beta$ unsaturated imines) $\mathbf{2 5 4}$ can react with an enamine $\mathbf{2 5 6}$ as the dienophile in order to form the desired piperidine ring in good regio- and stereo-selectivity (Scheme 39). ${ }^{119}$ Indeed, the enamine $\mathbf{2 5 6}$ can also be formed in situ by using an aldehyde and a proline-derived organocatalyst. ${ }^{120}$

Scheme 39. An aza-Diels-Alder reaction between an azadiene 254 and an enamine 256.

A further example of the use of organocatalyst $\mathbf{2 0 5}$ has been shown by Chen et al. in the presence of benzoic acid within the aza-Diels-Alder reaction of aldehydes $\mathbf{2 5 9}$ and aza-dienes 260. ${ }^{121}$ The piperidine ring product 261 subsequently undergoes an intramolecular hemiacetal formation to $\mathbf{2 6 2}$, which can then be oxidised to give the lactone 263 (Scheme 40). High yields of $90 \%$ were obtained using MeCN as the
solvent, whilst THF gave low yields of $30 \%$. MeOH , toluene and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ gave similar high yields of $81-83 \%$, with good efficiency and excellent stereocontrol.

Scheme 40. Formation of lactones 263 via the aza-Diels-Alder reaction.

These types of lactone-piperidine containing compounds are frequently observed within natural products. Examples include the biologically active marine natural product class of zoanthamines $264,{ }^{122}$ and the alkaloid lycojapodine A 265, which acts as an inhibitor towards acetylcholinesterase and HIV-1. ${ }^{123}$

264

265

The direct cycloaddition of $\mathbf{2 6 7}$ onto activated enamines is not normally an effective strategy via enamine activation. ${ }^{124}$ Reasons are given that this may be due to selfcondensation, oligomerisation, as well as poor stereocontrol. ${ }^{125}$ Despite this, Chen et al. have also demonstrated that acetaldehyde 267 can be used in the inverse-electrondemand aza-Diels-Alder reaction with azadiene coumarin derivative 266 to form piperidine rings 269. ${ }^{126}$ This reaction was catalysed by proline-type organocatalyst
$\mathbf{2 6 8}$ ( $20 \mathrm{~mol} \%$ ) and benzoic acid ( $20 \mathrm{~mol} \%$ ) and gave good yield and high ee after 24 hours. The newly formed piperidine ring 269 was subsequently dehydroxylated to 270 to aid with the analysis (Scheme 41). Hence, this reaction used the coumarin skeleton 266, a natural product first isolated in 1830 from tonka beans. ${ }^{127}$ Its derivatives exhibit broad biological activities, ranging from anti-inflammatory agents ${ }^{128}$ and coronary vasodilators, ${ }^{129}$ to tautomerase inhibitors ${ }^{130}$ and selective FXIIa inhibitors. ${ }^{131}$

Scheme 41. The use of coumarin derivatives 266 within the aza-Diels-Alder reaction.

If the carbonyl double bond of an aldehyde $\mathbf{8}$ is specifically used as the dienophile, 1,3-oxazinan-4-ones 273 can be formed with electron-rich azadienes 271 in the presence of a Rhodium catalyst. Hashimoto et al. have shown that this reaction proceeds exclusively in an endo mode to give the desired product in high yields and high levels of enantioselectivity. ${ }^{132}$ Only $1 \mathrm{~mol} \%$ of $\mathrm{Rh}_{2}(S$-BPTPI) 4 (dirhodium(II) tetrakis[ $N$-benzene-fused-phthaloyl-( $(S)$-piperidinonate]) was necessary to catalyse the reaction (Scheme 42).

Scheme 42. Catalytic asymmetric hetero-Diels-Alder reaction between azadiene 271 and aldehydes 8 .

If an alkyne is used as the dienophile instead of an olefin, no extra catalysts are normally needed to make the reaction cyclise. ${ }^{133}$ For example, Kim et al. have shown that 1,4-dihydropyridine 276 can be formed either by heating the reaction mixture under reflux ${ }^{134}$ or by microwave irradiation. ${ }^{135}$ Through these methods, they were able to synthesise Amlodipine ${ }^{136} 277$ after four extra steps. This is a compound that acts as a $\mathrm{Ca}^{2+}$ blocker ${ }^{137}$ and hence, is currently used as an antihypertensive drug. ${ }^{138}$

Scheme 43. Synthesis of amlodipine 276 via an aza-Diels-Alder reaction between 1azadiene 275 and alkyne 274.

A further interesting example using an alkyne 281 as a dienophile is shown by Singh et al. through a three-component one-pot reaction, whereby the 1 -azadiene $\mathbf{2 8 0}$ is formed in situ by reacting pyrido[2,3-d] pyrimidine 279 with an aldehyde 8 in the presence of catalytic amounts of L-proline 152. Through this method, the organocatalyst 152 forms an iminium ion 278 with the aldehyde 8 , thus making it sufficiently electrophilic for a conjugate addition to take place with the enamine 279 in order to form the 1-azadiene 280. Reaction with the alkyne 281 subsequently affords the aza-Diels-Alder product 282 (Scheme 44). ${ }^{139}$ These compounds containing the pyrido $[2,3-d]$ framework are biologically important, with numerous examples known to show different pharmacological properties, such as antibacterial, ${ }^{140}$
antitumour, ${ }^{141}$ cardiotonic, ${ }^{142}$ antialergic, ${ }^{143}$ antimalarial, ${ }^{144}$ analgesic, ${ }^{145}$ antifungal properties ${ }^{146}$ and as a CNS depressant. ${ }^{147}$

Scheme 44. An organocatalysed route to construct the pyrido $[2,3-d]$ framework 282, the reaction being performed at reflux.

2-Azadienes have also been reported to undergo inverse electron demand aza-DielsAlder cycloadditions when using a suitably active dienophile species in the presence of an appropriate acid. These 2-azadiene species are typically an imine where the nitrogen is protected with an aromatic group and thus, one double bond within the aromatic ring forms part of the diene (283). Examples of the dienophile include 3,4-dihydro-2H-pyran $\mathbf{2 8 4}{ }^{148}$ or 2,3-dihydrofuran $\mathbf{2 8 5}^{149}$ as the dienophile (Scheme 45) and hence, this method effectively synthesises a fused tricyclic compound (286-288) with good regioselectivity. Interestingly, varying the temperature can also control the stereoselectivity (compare 286 with 287). Additionally, the diene can also be formed in situ by reacting an aldehyde with a primary amine attached to an aromatic ring, such as aniline. ${ }^{150}$

Similar reactions are observed when using an alkyne 289 as the dienophile, either intermolecularly ${ }^{151}$ or intramolecularly, ${ }^{151,}{ }^{152}$ with the piperidine ring 290 being formed in good yield and regioselectivity. Interestingly, where an alkyne is used instead of an olefin 284 or 285, the ring containing the nitrogen aromatises to give the observed product 290 (Scheme 45).

Scheme 45. Aza-Diels-Alder reactions using 2-azadienes.

Boronates 293 derived from imines have also been shown to be effective in the formation of piperidine rings in order to access functionalised dihydroquinolines 295, whereby the imine is essentially part of a 2 -azadiene unit. ${ }^{153}$ In these cases, the imine nitrogen 293 coordinates to and polarises the $\mathrm{C}=\mathrm{N}$ bond. This, in turn, increases the reactivity of the arylamine towards the imino-Diels-Alder reaction (However, this route is limited to specific imines that are capable of forming the boronate) (Scheme 46).

Scheme 46. Piperidine ring formation using boronic acids.

Once the boronate complex 293 was formed, a diene could cyclise with the activated imine bond, thus forming the unsaturated piperidine ring 296 (Scheme 47). This reaction proceeded by inverse electron demand, because the 2 -azabutadiene system present in the boronates was electron deficient and it reacted with butadiene as the dienophile. Subsequent hydrolysis under basic conditions afforded the desired dihydroquinolines 295.

Scheme 47. Mechanism for the formation of piperidine rings via a boronate complex.

### 1.7 Other ways of forming piperidine rings

Whilst looking into the formation of $\beta$-amino ketones from ketones and aromatic imines via a Mannich reaction induced by radicals, Wang et al. found that piperidine rings $\mathbf{3 0 7}$ could also be formed by this method. ${ }^{154}$ To form their $\beta$-amino ketones 303, the imine $\mathbf{3 0 0}$ was activated by a radical cation salt (TBPA+), whilst the tautomerisation of the ketone $\mathbf{2 9 8}$ to the enol $\mathbf{2 9 9}$ was aided with a Lewis acid. Hence, the activated starting materials reacted with each other to give the desired $\beta$-amino ketone 303. Depending on the aromatic substituent of the imine, $\mathbf{3 0 3}$ could react further to form piperidine 307. Formation of this ring structure was dependent on having a $p-\mathrm{NO}_{2}$ group on $\mathrm{Ar}^{1}$. This was thought to be due to the increased electrophilicity of the radical cation intermediate $\mathbf{3 0 1}$ that the electron-withdrawing group brings, thus making the second addition to the enol tautomer of $\mathbf{3 0 3}$ more favourable. Electron transfer followed by intramolecular substitution then afforded the piperidine ring 307 in mild yields of 18-48\% (Scheme 48).

Scheme 48. A radical initiated aza-Diels-Alder reaction.

Through the use of azomethine ylids 309, aza-Diels-Alder cyclisation reactions are also possible in an intramolecular fashion, where the imine and enone are tethered together as one starting material 308. Hence, the stereochemistry of the product $\mathbf{3 1 0}$ is locked in place from the start. Gin et al. have used this idea in their quest for the first non-racemic synthesis of stemofoline, ${ }^{155}$ a biologically active alkaloid first isolated in 1970 by Irie and co-workers. ${ }^{156}$ Thus, in the presence of trifluoromethanesulfonic
anhydride $\left(\mathrm{Tf}_{2} \mathrm{O}\right)$ and tetrabutylammonium triphenyldifluorosilicate (TBAT), the carbonyl oxygen conjugated with the amine in $\mathbf{3 0 8}$ was activated, followed by desilylation with the anhydrous fluoride source to form the azomethine ylid 309. It was thought that this was followed by an intramolecular [3+2]-cyclisation in order to stereoselectively afford the desired polycyclic alkaloid 310 in good yield (71\%) (Scheme 49). Equation 24 shows the proposed interaction prior to cyclisation.

Scheme 49. An aza-Diels-Alder reaction going via an azomethine ylid intermediate.

Equation 24

Additionally, piperidine rings can also be formed via routes that do not involve the Mannich reaction. These include: 1) ring formation via alkylation of a nitrogen centre with an acyclic precursor containing pre-established stereogenic centres; 2) asymmetric generation of stereocentres and substitution patterns on an existing sixmembered heterocycle; 3) ring expansion of pyrrolidine or furan derivatives; and 4) ring closing-metathesis on dialkyl substituted nitrogen derivatives where each alkyl group contains an appropriately positioned alkene functional group. ${ }^{157}$

### 1.6 Summary

In summary, the present evidence suggests that the aza-Diels-Alder reaction of electron rich dienes with imino dienophiles proceeds via a Mannich-Michael process as opposed to a concerted mechanism. This is largely supported by the presence of Mannich-intermediates, which have been isolated within reaction mixtures. Generally, Lewis acids or organocatalysts catalyse this reaction.

With the use of Lewis acids, activated enones in the form of the Danishefsky's diene have traditionally been necessary, along with stoichiometric amounts of the Lewis acid. However, with more recent optimised examples, the Lewis acids have been shown to be effective in catalytic amounts using enones as the diene, although a secondary acid is sometimes needed to activate the enone to the enol. With regards to the reaction conditions, a lower temperature in general gives higher stereoselectivity. Conversely, a lower temperature also lowers the yield obtained, hence a compromise is usually reached between $0{ }^{\circ} \mathrm{C}$ to room temperature. Depending on the Lewis acid used, different polarities of solvent are effective. For example, $\mathrm{Zn}(\mathrm{II})$ catalysts tend to operate more effectively in polar solvents, whereas phosphoric acid catalysts prefer non-polar solvents. Additionally, the diene used seems to be limited to the electron rich Danishefsky diene or cyclic enones.

The use of organocatalysts in the aza-Diels-Alder reaction has only been investigated in the last decade. Higher catalyst loadings are needed compared to their individual Mannich and Michael reaction counterparts and this is due to the increased steric congestion. Proline-derived organocatalysts seem to work well here, although if the catalyst has no acidic character, then an additional catalytic amount of acid tends to be needed in the reaction. The main disadvantages of using organocatalysts are the necessity of including a large excess of enone (typically 4 equivalents, although sometimes as much as 30), as well as their low reactivity; many days are required for the reactants to cyclise. As a result, the reactions are normally carried out at room temperature. Additionally, it seems to be of preference to abstain from having aromatic groups on the nitrogen of the imine.

Nonetheless, the field of the aza-Diels-Alder reaction is still in its infancy, and no doubt the same advances will be seen with the use of organocatalysts as have been seen with Lewis acids. ${ }^{116}$ After all, industry is always looking into new ways of constructing these rings asymmetrically to make the synthesis of highly functionalised piperidines more efficient and versatile.

Chapter 2:

## AIMS AND OBJECTIVES

## 2. Aims and Objectives

The piperidine ring is an important moiety found in countless natural products, many of which are biologically active. Examples include: nicotine 310; ${ }^{158}$ the fire ant toxin solenopsin 311; ${ }^{159}$ and the alkaloid ( $S$ )-scoulerine 312, ${ }^{160}$ a natural medicinal compound acting as an adrenoceptor and $5-\mathrm{HT}$ receptor antagonist (Figure 1). An atom-economical route for the formation of these biologically active piperidine ring systems could be via an aza-Diels-Alder pathway.

311

312

Figure 1. Examples of different biologically active piperidine rings.

By using metal- or organo-catalysis in an aza-Diels-Alder reaction, different piperidine ring systems could be synthesised and subsequently manipulated to form the biologically active compound of ones choice (Scheme 50). The metal catalysed aza-Diels-Alder reaction has been known for some time, ${ }^{116}$ whilst the more recent organocatalytic route is currently a slower and less efficient process, requiring a large excess of enone (4-30 equivalents) ${ }^{9}$ and long reaction times (1-7 days), ${ }^{91}$ with varying yield ranges of isolated compound obtained. Hence, there is a need to make the aza-Diels-Alder reaction cleaner, greener and more robust.

For the aza-Diels-Alder reaction, current procedures mainly rely on using Lewis or Brønsted acids as catalysts, with limited procedures available for the use of organocatalysts. Hence, a main objective of this research was to investigate, with the aim of improving, the organocatalysed aza-Diels-Alder reaction.

Scheme 50. aza-Diels-Alder routes using different catalysts.

A desired method to perform an atom-economical aza-Diels-Alder reaction would be to react an amine, aldehyde and ketone together in a one-pot, three-component system; thus eliminating the need to pre-form the imine and saving time and money in the process. Hence, the first aim in this project was to probe how viable this method was by determining whether a broad selection of amines, aldehydes and ketones could react together in this way. Further investigations would determine what reaction conditions and substrate limitations were important within the aza-Diels-Alder reaction.

The approach towards the development of an asymmetric organocatalytic aza-DielsAlder reaction was based on imminium catalysis and Lewis acid activation through boronic acids 315. These bifunctional aminoboronic catalysts have recently been shown to give high asymmetric induction for the aldol reaction (Scheme 51). ${ }^{161}$ Hence, a further aim of this project was to synthesise and compare these bifunctional aminoboronic acids with other more established pyrrolidine-derived organocatalysts to see if these acids could be better suited for the aza-Diels-Alder reaction.

Scheme 51. Example of aminoboronic acid reactivity in the aldol reaction.

For the aza-Diels-Alder reaction, it was believed that the reaction would go through a stepwise Mannich-Michael process via transition state 321 (Scheme 52). Hence, the Mannich and Michael reactions would be individually investigated in order to determine what characteristics of the aminoboronic acid would be important in order to make this a successful catalyst for the aza-Diels-Alder reaction.

Scheme 52. Proposed aza-Diels-Alder reaction using bifunctional aminoboronic acids as catalysts.

There is substantial industrial interest in advancing the field of piperidine ring formation, due to the medicinal properties that such piperidine ring-containing compounds possess. Hence, the development of a robust, efficient and general organocatalytic aza-Diels-Alder process has the potential to make a considerable impact within industry by lowering costs, saving time and improving on their green ratings through following procedures that are more environmentally friendly.

Chapter 3:
RESULTS AND DISCUSSION

## 3. Results and Discussion

### 3.1 Synthesis of Precursor Reagents

### 3.1.1 Imine Formation

Imines are typically synthesised by the condensation of primary amines and aldehydes. In terms of mechanism, such reactions proceed via a nucleophilic addition giving a hemiaminal intermediate, followed by elimination of water to afford the imine. A catalyst and/or a drying agent is typically used to help drive the equilibrium in favour of imine formation.

A selection of different imines were synthesised from their aldehyde and amine starting components in the presence of a drying agent, with the results tabulated in Table 1.

Imines 323, 324, 326, 75 and 328 were relatively straightforward to synthesise and purify following literature procedures. ${ }^{162}$ However, the synthesis of imine $\mathbf{3 3 0}$ proved to be unsuccessful (Table 1, Entry 7), whilst a low yield of $23 \%$ was obtained with imine 155 (Table 1, Entry 6). This can be attributed to one of the side-products of this reaction, 331; a solid that was isolated from the crude oil reaction mixture and which was subsequently characterised. Two $p$-anisidine $\mathbf{1 2 0}$ units were consumed for every aldehyde 329 unit in order to make 331. In the ${ }^{1} \mathrm{H}$ NMR of 331, it is interesting to note that the NH proton is located in the 9 ppm region, which is further downfield than is expected for a simple amide. To confirm this assignment, a $\mathrm{D}_{2} \mathrm{O}$ shake was performed on 331 in $\mathrm{CDCl}_{3}$ to form 332 (Equation 25), whereby the NH peak at $\delta=9$ ppm disappeared, showing that hydrogen to deuterium exchange had taken place confirming the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{3 3 1}$.

Table 1. Synthesis of different imines.

Entry \begin{tabular}{ccccccc}

Aldehyde \& Amine \& Solvent | Drying |
| :---: |
| Agent | \& Product \& Yield <br>

\hline
\end{tabular}

It is also interesting to note that compound $\mathbf{3 3 1}$ had only been mentioned once before in the literature. ${ }^{163}$ This was in a 1976 Russian paper looking into the association and mesomorphism of amido nitrones using infrared (IR) spectroscopy, in which only the IR and melting point of $\mathbf{3 3 1}$ were reported.

## Equation 25

In order to compare configurationally locked imines to acyclic ones, the synthesis of cyclic imines 243, 246, 333 and 334 were also explored.

243

246

333

334

Imine 243 was synthesised in two steps in accordance with literature methods (Scheme 53). ${ }^{164}$ Hence, 2-phenylethylamine 335 was heated neat with excess ethyl formate 336, after which the excess ethyl formate was evaporated in vacuo to give the crude product. Purification using Kugelrohr distillation gave pure formamide 337 as a mixture of rotamers (around the amide bond) in the ratio 5:1 ( ${ }^{1} \mathrm{H}$ NMR). ${ }^{1} \mathrm{H}$ NMR experiments carried out in DMSO were performed at $\mathrm{rt}, 50^{\circ} \mathrm{C}$ and $100{ }^{\circ} \mathrm{C}$ in an attempt to determine whether the rotameric species would interconvert. However, this did not occur, although the amide NH and $\mathrm{CH}_{2}$ resonances did change chemical shift at different temperatures. Subsequent intramolecular cyclisation of formamide 337 was straightforward in polyphosphoric acid to give the pure imine 243.

Scheme 53. Synthesis of cyclic imine 243.

Imine 246 was synthesised in a similar fashion whereby formamide $\mathbf{3 3 9}$ was formed after refluxing tryptamine $\mathbf{3 3 8}$ with excess ethyl formate 336. ${ }^{165}$ However, cyclisation of formamide 336 using polyphosphoric acid at elevated temperatures proved challenging. Hence, phosphorus(V) oxychloride was used instead, in accordance with a procedure reported by O'Rell et al., ${ }^{166}$ in order to afford the desired imine 246.

Scheme 54. Synthesis of cyclic imine 246.

The synthesis of imine $\mathbf{3 3 3}$ was also straightforward following literature procedures, i.e. by reacting piperidine $\mathbf{3 4 0}$ with $N$-chlorosuccinimide (NCS), followed by treatment of the obtained chlorinated amine $\mathbf{3 4 1}$ with a base. ${ }^{167}$ However, the product $\mathbf{3 3 3}$ was obtained as part of a mixture with its dimer $\mathbf{3 4 2}$ and trimer $\mathbf{3 4 3}$ forms; these species were confirmed by MS, IR and NMR.

Scheme 55. Synthesis of cyclic imine 333.

In order to compare six-membered cyclic imines with five-membered ones, the synthesis of imine $\mathbf{3 3 4}$ was also attempted. Imine $\mathbf{3 3 4}$ with the di-methyl group on the 3'-position was chosen, as this would prevent the imine tautomerising to the aromatic indole. Hence, the synthesis of $\mathbf{3 3 4}$ was attempted following a patent procedure starting with phenylhydrazine 344 and isobutyraldehyde $\mathbf{3 4 5}$, with the intermediate 346 being cyclised in the presence of methanesulfonic acid (Scheme 56). ${ }^{168}$ LCMS of
the crude reaction mixture showed the presence of the imine 334. However, attempts to purify this compound proved futile and the imine 334 was not isolated.

Scheme 56. Attempted synthesis of imine 334.

### 3.1.2 Electron-Rich Diene Formation

Electron-rich dienes were needed for the comparison of the organocatalytic aza-DielsAlder reaction with the Lewis-acid catalysed reaction. Hence, these dienes 347 were synthesised from their corresponding enones $\mathbf{1 8 3}$ (Table 2). ${ }^{15,169}$

Table 2. Synthesis of electron-rich dienes.

| Entry | Enone | Conditions | $\begin{gathered} \text { Diene } \\ \text { (\% Isolated Yield) } \end{gathered}$ | Main Impurity |
| :---: | :---: | :---: | :---: | :---: |
| 1 |  | $\stackrel{\mathrm{DBU}}{\mathrm{rt}, \mathrm{CH}_{2} \mathrm{Cl}_{2}}$ |  |  |
| 2 |  | $\mathrm{NEt}_{3}$, dry $\mathrm{ZnCl}_{2}$ $40^{\circ} \mathrm{C}$, Diethyl ether |  |  |
| 3 |  | $\mathrm{NEt}_{3}$, dry $\mathrm{ZnCl}_{2}$ $40^{\circ} \mathrm{C}$, Diethyl ether |  | $\mathrm{NEt}_{3}$ |

These reactions were found to be challenging; the dienes were easily hydrolysed to their corresponding enones, meaning care was needed to prevent this happening. In
addition, the dienes and their corresponding enones had very similar properties, making it a challenge to separate them from each other. These problems were partly circumvented by performing the reaction under inert conditions using anhydrous reagents, and by purifying by vacuum distillation.

Synthesis of diene $\mathbf{3 5 1}$ from enone $\mathbf{1 6 4}$ was attempted under inert conditions (Table 2, entry 3). However, purification proved to be challenging; the boiling point of diene 351 was too high for atmospheric distillation and too low for a facile reduced pressure distillation (lit. $\mathrm{bp}=25-28{ }^{\circ} \mathrm{C}, 16 \mathrm{mbar}$ ). ${ }^{170}$ Control of the vacuum was attempted using a bleed in the apparatus. Despite this, diene $\mathbf{3 5 1}$ was obtained contaminated with triethylamine.

### 3.1.3 Chalcone Formation

In order to determine whether the electronics of the enone may have a significant effect within the aza-Diels-Alder reaction, chalcones 169 with different electronics were synthesised from acetone $\mathbf{3 1 4}$ and their corresponding aldehydes $\mathbf{1 1 2}$ via an aldol condensation reaction (Table 3). ${ }^{171}$

Table 3. Synthesis of different chalcones.
Entry

Thus, in addition to the electronically neutral enone 348, the electron-donating enone 353 and the electron-withdrawing enone 355 were synthesised from aldehydes 322, 352 and 354 respectively, with excess acetone 314 in (aq) NaOH (Table 3).

### 3.2 Aza-Diels-Alder Screening Studies

### 3.2.1 Screening of the One-Pot, Three-Component aza-Diels-Alder Reaction

A straightforward way to synthesise piperidine rings via an aza-Diels-Alder reaction would be to react a ketone with an amine and an aldehyde in the presence of a suitable catalyst. In order to help determine the robustness of this methodology, sets of different enones 183, aldehydes $\mathbf{8}$ and amines $\mathbf{8 6}$ were screened in the presence of an organocatalyst in different solvents (Table 4).

Table 4 (a). Tabulated results for the one-pot, three-component screening reactions.

${ }^{*} \mathbf{A}=$ the number of starting reagents completely consumed
$\mathbf{B}=$ the number of prominent/interesting new spots observed
$\mathbf{C}=\mathrm{TLC}$ analysis suggesting a good, clean reaction $(\mathrm{Y}=\mathrm{yes}, \mathrm{N}=\mathrm{no})$.

Enones 164, 350, and 348 were chosen due to their ability to form piperidine rings with different degrees of saturation and substitution. Aldehydes 322, 329, and 327 were chosen for their electronic properties to form imines with varying levels of electronics. Amines $\mathbf{1 2 0}$ and $\mathbf{1 8 6}$ were chosen to determine how aromatic amines compare versus allylic ones. The organocatalysts $\mathbf{1 5 2}$ and $\mathbf{3 5 6}$ were chosen in order to compare the default organocatalyst of choice: L-proline 152, against its unfunctionalised analogue, pyrrolidine 356. These compounds were screened against each other in small vials at room temperature, monitoring the reactions over a period of 24 and 48 hours by thin layer chromatography (TLC).

From these screening reactions (Table 4), it was apparent that most of the combinations of reactants afforded either multiple products or none at all; they did not form clean, robust, kinetically controlled reactions. This suggested that formation of
the imine beforehand could have been a better approach for the study of this reaction. Indeed, the one-pot, three-component reactions in the literature are usually performed after optimisation with the pre-formed imine. ${ }^{92}$

From the complex array of spots on the TLC plates, it was possible to deduce some further findings. The reactions using L-proline $\mathbf{1 5 2}$ as catalyst tended to consume the starting materials more rapidly than those using pyrrolidine 356. This suggested that the acidic character of L-proline $\mathbf{1 5 2}$ was important. Regarding solvents, better reactivity was observed when using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, the opposite being true when using THF. Allylamine 186 gave cleaner reactions compared to aromatic amine 120, as did the use of benzaldehyde $\mathbf{3 2 2}$ over ethyl glyoxylate 329. In terms of the enones used, methyl vinyl ketone 164 was the least reactive, whereby most of the TLC spots observed were starting material spots. The Ph $\mathbf{3 4 8}$ and OMe $\mathbf{3 5 0}$ enones seemed to be similarly reactive to each other.

In order to determine whether the two-component reaction between an imine and an enone was cleaner than the three-component reaction, a further screening study was carried out whereby the imines were formed in situ prior to addition of the enone and catalyst. $3 \AA$ Molecular sieves (M.S.) were used to aid with the imine formation by helping to remove water. After 48 hours, an enone and catalyst 152 ( $20 \mathrm{~mol} \%$ ) were added to the reaction mixture (Table 5). These reactions were monitored by TLC, whereby fewer minor spots were observed compared to the one-pot, three-component system. These results further suggested that pre-formation of the imine did lead to cleaner reaction outcomes.

### 3.2.2 Screening Using Imines

Through the previous screening studies (Table 5), it was determined that the study of the aza-Diels-Alder reaction was better approached through the use of imines in a two-component reaction. Hence, the pre-formed acyclic imines 11 (Table 1) were screened in the aza-Diels-Alder reaction with enones $\mathbf{1 8 3}$ in order to determine if a combination of these would afford clean reactions to the desired piperidine ring product 313. The reactions were performed in the presence of $3 \AA$ molecular sieves in order to limit the amount of imine $\mathbf{1 1}$ hydrolysing back down to its corresponding amine $\mathbf{8 6}$ and aldehyde $\mathbf{8}$. These screening reactions were performed in small vials at room temperature, with each reaction being monitored after 24 and 48 hours via TLC. The different combinations of enone to imine, catalyst and solvent used are tabulated in Table 6. In this set of screening reactions, THF was not used because this solvent had proved to be less effective for the one-pot, three-component screening reactions (Table 4).

* $\mathbf{A}=$ the number of starting reagents completely consumed
$\mathbf{B}=$ the number of prominent/interesting new spots observed
$\mathbf{C}=$ TLC analysis suggesting a good, clean reaction $(\mathrm{Y}=\mathrm{yes}, \mathrm{N}=\mathrm{no})$.

The results obtained from the imine screening reactions (Table 6) generally showed that cleaner reactions were taking place via TLC analysis, compared to the one-pot, three-component reactions. However, it was also observed that these reactions were slow, none of which went through to completion (single spot) after 48 h . These screening results also seemed to agree with the one-pot, three-component screening results, i.e. that $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ seemed to be a better solvent to use compared with MeOH , and that L-proline $\mathbf{5 2}$ seemed to be a more active catalyst than pyrrolidine 356. Methyl vinyl ketone 164 was the least reactive of the enones, whilst the most promising results seemed to be obtained when the allylic imines $\mathbf{3 2 4}$ and $\mathbf{3 2 8}$ were used.

The main challenge in analysing these screening reactions via TLC analysis was in determining which of the newly observed spots was the desired piperidine ring product 313, if any. Hence, it was immediately apparent that the piperidine rings 313
needed to be individually synthesised to obtain a set of standards, which could be used as a references in order to aid in the identification of the product. It was decided to synthesise the piperidines using two methods: a) an organocatalytic pathway using enones and L-proline; and b) a more traditional Lewis acid-catalysed pathway using electron-rich dienes.

### 3.3 Initial Piperidine Ring Formation Attempts

### 3.3.1 Attempted Piperidine Ring Formation Using Organocatalysts

Having all the starting materials at hand, the synthesis of piperidine standards 313 was attempted from their corresponding imines 11 and enones 183 and the readily accessible L-proline $\mathbf{1 5 2}$ was used as an organocatalyst. This was carried out in order to aid with product identification by having the pure compound at hand. Hence, $R_{f}$ values could be compared whilst the NMR spectrum could be used to assist in identifying and isolating these products from the organocatalysed reaction attempts.

Table 7. Piperidine ring formation attempts using organocatalysts.

| Entry | Imine | $\mathrm{R}^{1}$ | $\mathrm{R}^{2}$ | Enone | $\mathrm{R}^{3}$ | Solvent | $3 \AA$ <br> M.S. | Products |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathbf{3 2 4}$ | Allyl | Ph | $\mathbf{3 4 8}$ | Ph | MeOH | No | $\mathbf{3 5 7}$ |

| 6 | $\mathbf{3 2 8}$ | Allyl | $(\mathrm{MeO})_{2} \mathrm{CH}$ | $\mathbf{3 4 8}$ | Ph | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | Yes | Mannich |
| 7 | $\mathbf{3 2 4}$ | Allyl | Ph | $\mathbf{3 5 3}$ | PMP | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | Yes | - |
| 8 | $\mathbf{3 2 4}$ | Allyl | Ph | $\mathbf{3 5 5}$ | PNP | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ | Yes | - |

Synthesis of piperidine $\mathbf{3 5 7}$ (Table 7, entry 1) was chosen because it was the example in the literature that gave the highest yields $(77 \%) .{ }^{92}$ Hence, 357 was synthesised with an adequate yield of $43 \%$, with the ${ }^{1} \mathrm{H}$ NMR spectra confirming the relative stereochemistry: the proton peak at $\mathrm{Ph} H \mathrm{CN}$ was a clear doublet of doublets [ $\delta=3.94$ (dd, $J=12.0,3.0 \mathrm{~Hz}, 2 \mathrm{H}$ )], which suggested that it was symmetric, i.e. both the Ph groups being cis to each other (Figure 2).

Figure 2. Proposed relative stereochemistry of compound 357.

The use of aromatic group PMP on the $\mathrm{R}^{1}$ position of the imine was also explored (Table 7, entries 2 and 4). It was known in the literature that these groups were relatively simple to remove from the nitrogen at a later stage. ${ }^{61}$ However, the desired piperidine ring products could not be isolated. The difficulty in obtaining these piperidine compounds through this method was re-enforced in the literature, ${ }^{92}$ where it was noted that the piperidine was often a minor product, with only $21 \%$ yield being obtained. This may be due to the imine being too electron-rich due to the methoxy group in the para position of the $\mathrm{R}^{1}$ aromatic, and hence, not sufficiently nucleophilic to go through with the initial Mannich reaction.

The examples shown in Table 7, entries 3 and 4, were chosen due to the interesting LW UV active spots observed by TLC analysis when screening the one-pot, threecomponent screening reactions (Table 4). However, neither of the piperidines were isolated. Instead, the major new compound in both sets of reactions was the vinylogous amide 358. It was proposed that in order to form 358, the imine $\mathbf{3 2 4}$ had to have hydrolysed to the corresponding aldehyde 322 and amine 186 units, with the free amine 186 subsequently performing a Michael addition to the enone 350 and elimination of methanol to form the vinylogous amide 358.

Scheme 57. Proposed route for the formation of 358.

In order to confirm that the vinylogous amide 358 was formed from amine 186 and enone 350, 186 and $\mathbf{3 5 0}$ were dissolved in $\mathrm{CDCl}_{3}$ in an NMR tube. After 20 hours, it
was observed by ${ }^{1} \mathrm{H}$ NMR that amine $\mathbf{1 8 6}$ had reacted quantitatively with enone $\mathbf{3 5 0}$ to form 358 (Equation 26). These results showed the importance of keeping these reactions dry, a process that could be performed through the use of molecular sieves.

Equation 26

Table 7, entry 3 also showed a minor compound that was believed to be 360 (3\% yield). It was thought that imine 324 was sufficiently nucleophilic to perform a Mannich reaction with the enone $\mathbf{3 5 0}$ to form the adduct 359, with this Mannich adduct subsequently performing a Michael vinyl ether addition with methanol (solvent) in order to form $\mathbf{3 6 0}$ (Scheme 58). This result demonstrated the challenge of having an active catalyst that is able to efficiently perform a Mannich followed by an intramolecular Michael reaction to form a piperidine ring, without stalling in the middle of the reaction sequence.

Scheme 58. Possible reactions from the Michael adduct 359.

From the imine screening experiments (Table 6), it was thought that methyl vinyl ketone $\mathbf{1 6 4}$ could give promising results when reacted with imine 328. However,
when imine 328 was reacted with methyl vinyl ketone $\mathbf{1 6 4}$, no piperidine product $\mathbf{3 1 3}$ was isolated (Table 7, entry 5).

The reactions between imines $\mathbf{7 5}$ and $\mathbf{3 2 8}$ with enone $\mathbf{3 4 7}$ also seemed promising (Table 6). However, when the reactions were scaled up (Table 7, entry 6), again no piperidine product $\mathbf{3 1 3}$ was isolated. Instead, in the reaction with imine 328, the main intermediate observed was a highly polar compound where spectroscopic evidence suggested this was the uncyclised product 363. This was proposed due to: a) high solvent polarities that were needed to flush the mixture containing 363 when purifying by silica gel chromatography ( $11 \%$ yield); and b) the ${ }^{1} \mathrm{H}$ NMR showed an AB conjugated trans-alkene system [ $\delta 6.53(\mathrm{~d}, J=16.3 \mathrm{~Hz}, 1 \mathrm{H}), 6.26(\mathrm{~d}, J=16.3 \mathrm{~Hz}$, $1 \mathrm{H})$ ]. Apart from some allylic peaks, it was hard to tell what the rest of the peaks in the spectra belonged to. This result again hinted at the challenge of making the catalyst sufficiently reactive to catalyse the intramolecular cyclisation to the piperidine.

363

In the attempted formation of $\mathbf{3 1 3}$ from $\mathbf{3 5 3}$ (Table 7, entry 7), the electron-rich enone 353 seemed to be inactive and did not react with imine 324. Indeed, after 1 week of stirring at room temperature, only the starting materials $\mathbf{3 5 3}$ and $\mathbf{3 2 4}$ were observed in the reaction mixture. This might be due to the electron-donating methoxy group of 353 stabilising the iminium ion that the catalyst would have formed with the enone.

In the attempted formation of piperidine $\mathbf{3 1 3}$ from electron-deficient enone $\mathbf{3 5 5}$ (Table 7, entry 8), two new minor spots were observed after 48 hours by TLC analysis. However, after subsequent purification via silica gel chromatography, it was found that neither of these new spots were 313, as there was no characteristic allylic peaks observed in the ${ }^{1} \mathrm{H}$ NMR spectrum. However, it could not be determined what these
minor spots corresponded to because of the large array of complex peaks present in their ${ }^{1} \mathrm{H}$ NMR's.

### 3.3.2 Attempted Piperidine Ring Formation Using Lewis Acids

Building up a library of piperidine standards $\mathbf{3 1 3}$ using L-proline $\mathbf{1 5 2}$ as a catalyst had proved challenging. Hence, it was decided to follow the more traditional Lewis acid approach for the formation of systems 313 and 12, using electron rich dienes and imines in the presence of Lewis acids (Table 8). ${ }^{31,84}$

Table 8. Piperidine ring formation attempts using Lewis acids.

$\ddagger$ Unable to isolate the product from the crude reaction mixture.

* These compounds were not isolated $100 \%$ pure.

When using diene 349 and $\mathrm{ZnCl}_{2} \cdot \mathrm{Et}_{2} \mathrm{O}$ as Lewis acid, this being the catalyst of choice used by Kunz et al. in their aza-Diels-Alder reactions, ${ }^{30}$ the reaction seemed to be inactive with the substrates used (Table 8, entry 1). Hence, the reaction was attempted using $\mathrm{Yb}(\mathrm{OTf})_{3}$ (Table 8 , entries 2 and 3 ). Through comparing the crude ${ }^{1} \mathrm{H}$ NMRs
with the literature examples, ${ }^{49,}{ }^{61}$ it was found that piperidine products had been formed, however, they were mixed with starting enone 348. Purification by silica gel chromatography was challenging since enone $\mathbf{3 4 8}$ had a similar $R_{f}$ to the piperidine products, and hence, the piperidines were not isolated cleanly.

In the literature, there were only a few examples where the dienes such as $\mathbf{3 4 9}$ were used in the aza-Diels-Alder reaction; ${ }^{172}$ most of the Lewis acid catalysed aza-DielsAlder reactions seemed to use the more electron-rich Danishefsky's diene or a cyclic enone as the diene source. ${ }^{29}$ Hence, different imines were reacted with Danishefsky's diene with the aim of forming piperidines of type $\mathbf{1 2}$ (Table 8, entries 4-9).

Despite obtaining some of the desired piperidines, it was again challenging to purify and obtain them $100 \%$ pure (Table 8, entries 4-6). The use of more electron-rich imines (Table 8, entries 7-9) and an electron-deficient imine (Table 8, entry 9) were also investigated. However, mixtures of compounds were again formed, and the isolation of the corresponding products proved unsuccessful.

The difficulties encountered in synthesising piperidine standards confirmed the need to develop a more robust methodology for the efficient assembly of these heterocyclic rings via an atom-economical, aza-Diels-Alder pathway. In addition, it was observed that the pharmaceutical industry was particularly interested in the synthesis of piperidines that were fused to other aromatic rings, due to the special biological activities that they can exhibit. Examples include the VMAT2 inhibitor 365 that is used to diagnose Parkinson's disease, ${ }^{173}$ and the multi-cyclic compound 366 used to cleave DNA plasmids. ${ }^{174}$

365

366

As a result, it was decided to concentrate investigation efforts on forming the building block 244 as a simplified example of such multi-cyclic compounds via an aza-DielsAlder reaction, starting from the fused bi-cyclic imine 243 (Equation 27).

Equation 27

### 3.4 Formal [4+2]-Cycloadditions Using Dienes

Having experienced the challenges of synthesising piperidine standards from acyclic imines, it was deemed sensible to investigate the aza-Diels-Alder reaction using cyclic imines. This would produce fused-multicyclic piperidine rings, which are a class of compound the pharmaceutical industry is particularly interested in due to the biological activities they can exhibit. Hence, it was decided to explore the synthesis of polycyclic nitrogen heterocycles $\mathbf{3 6 8}$ starting from cyclic imines of type $\mathbf{3 6 7}$ (Equation 28). As a result, aza-Diels-Alder methodology was investigated in an attempt to find a general approach to dihydroisoquinoline-derived dihydropyridinones from formal aza-Diels-Alder adducts.

## Equation 28

Initially, 3,4-dihydroisoquinoline $\mathbf{2 4 3}$ was used as the imine equivalent of $\mathbf{3 6 7}$. This imine 243 was synthesised according to literature methods ${ }^{164}$ and subsequently reacted with Danishefsky's diene 4 in the presence of catalytic ytterbium(III) triflate in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, with the aim of forming piperidenone 244 . When this reaction was performed under air, there was no evidence that piperidenone 244 had been formed. However, when the reaction was performed under inert conditions, piperidenone 244 was formed and isolated, albeit in poor yield (Equation 29).

Equation 29

However, when imine 243 was reacted with one equivalent of Danishefsky's diene 4, it was observed that another compound was being formed which had an almost identical $R_{f}$ value to the piperidenone 244. In addition, it was observed that when more of the same batch of Danishefsky's diene 4 was used in the reaction shown in Equation 29, more of the mixture seemed to be contaminated with the side-product. MS and NMR studies suggested that the side-product was being formed from two enones and one imine. It was later confirmed by X-ray crystallography that the sidecompound being produced was the diacetyl-dihydropyridine 369 (Figure 3), arising from a formal $[2+2+2]$-cycloaddition; it was seen that its formation versus that of piperidenone 244 (a [2+4]-cycloaddition product) depended on the purity of Danishefsky's diene $\mathbf{4}$ and how easily hydrolysed it was under the reaction conditions. Hence, in order to fully understand what was happening, further studies were undertaken using both Danishefsky's diene 4 and the 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ (Table 9).

Figure 3. X-ray molecular structure of compound 369.

Table 9. Reaction of the imine 243 with the diene $\mathbf{4}$ and enone 350.

| Equivalents of 243 | Ratio of 244/369 <br> (total $=1.2$ <br> equivalents) | Yield of 244 (\%) | Yield of 369 (\%) |
| :---: | :---: | :---: | :---: |
| 1 | $1 / 0$ | 14 | None isolated pure |
| 1 | $1 / 0.25$ | None isolated pure | 20 |
| 1 | $0 / 1$ | 0 | 20 |

When using pure Danishefsky's diene 4 from a new commercial source, piperidenone 244 was obtained in $14 \%$ yield, with no diacetyl-dihydropyridine $\mathbf{3 6 9}$ being isolated (Table 9, entry 1). However, when Danishefsky's diene 4 was contaminated with 4-methoxy-3-buten-2-one 350 (6/1), piperidine ring 244 was obtained contaminated with the by-product 369 ( $20 \%$ yield) (Table 9, entry 2 ). In contrast, use of 4-methoxy-3-buten-2-one 350 in place of Danishefsky's diene 4 under identical reaction conditions (Equation 30) did not provide piperidenone 244. Instead, the only cleanly isolated product proved to be the diacetyl-dihydropyridine 369, clearly derived from the reaction of two equivalents of the 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ via an overall formal $[2+2+2]$-cycloaddition process.

Equation 30

Thus, it was seen that the prevalence of side-product 369 over piperidenone 244 occurred due to the facile hydrolysis of Danishefsky's diene 4 to 4-methoxy-3-buten-

2-one 350; the enone 350 being responsible for the formation of side product $\mathbf{3 6 9}$. Hence, in order to improve on the yield of piperidenone 244 (Equation 29), it was immediately apparent that the system needed to be as dry as possible in order to prevent hydrolysis of Danishefsky's diene 4. Thus, the reaction was screened using different Lewis acids in the presence of $3 \AA$ molecular sieves and 2-ethyl-2-oxazoline (to aid in solubility) in an attempt to determine which Lewis acids were more likely to catalyse the synthesis of piperidenone $\mathbf{2 4 4}$, and which were more likely to hydrolyse Danishefsky's diene 4 (Table 10). In all cases, the imine 243 was fully consumed within 72 h .

Table 10. Catalyst screening for the [4+2]-reaction, analysed by TLC after 72 h .

| Entry | Lewis Acid | Presence of Enone | Formation of [ $2+2+2$ ] product | Clear formation of $\mathbf{2 4 4}$ in good amounts |

| 5 | Fe (III) $\mathrm{Cl}_{3}$ | No | Yes | Very little |
| 6 | In (III) $\mathrm{Cl}_{3}$ | Yes | No | Yes-little |
| 7 | Sn (II) $\mathrm{Cl}_{2}$ | Yes | Yes | Yes |
| 8 | $\mathrm{Ru}(\mathrm{III}) \mathrm{Cl}_{3}$ | Yes | No | Yes |
| 9 | $\mathrm{Rh}(\mathrm{III}) \mathrm{Cl}_{3}$ | Yes | No | Yes |
| 10 | $\mathrm{Sc}(\mathrm{III})(\mathrm{OTf})_{3}$ | No | Yes | Yes |
| 11 | Ce (III) $\mathrm{Cl}_{3}$ | Yes | No | Yes |
| 12 | $\mathrm{In}(\mathrm{III})(\mathrm{OTf})_{3}$ | No | Yes | Yes |

Collectively, it was observed that the triflate-based catalysts (Table 10, entries 1, 10, 12) favoured the $[2+2+2]$-cycloaddition. This was not too surprising because even though these catalysts were more active compared to the chloride-based catalysts, they were very hygroscopic, meaning it was almost impossible to obtain them completely anhydrous; hence, these catalysts were discarded for use in the [4+2]cycloaddition reaction.
$\mathrm{RuCl}_{3}$ and $\mathrm{RhCl}_{3}$ gave similar results (Table 10, entries 8,9 ). However, considering rhodium was around 1000x more expensive than Ruthenium, the $\mathrm{RhCl}_{3}$ catalyst was also discarded.

The most promising catalysts that were chosen were: $\mathrm{CuCl}_{2}, \mathrm{CeCl}_{3}$, and $\mathrm{RuCl}_{3}$ (Table 10 , entries $3,11,8$ ). These were taken forward to a further set of screening reactions where different phosphine ligands were used to see whether these ligands would have any significant effect over 2-ethyl-2-oxazoline in terms of helping to catalyse the reaction (Table 11). The phosphine ligands used (Figure 4) were chosen due to them representing a range of mono- and bi-dentate systems.

## Figure 4

$\mathrm{CuCl}, \mathrm{InCl}_{3}$ and $\mathrm{ZnCl}_{2}$ were also taken forward to the next set of screening reactions (Table 11), as these were catalysts that had previously been used in similar reactions in the literature (using acyclic imines). ${ }^{116}$ It was also thought wise to include one triflate-based catalyst for comparison, thus $\mathrm{Sc}(\mathrm{OTf})_{3}$ was chosen as this catalyst
formed the least amount of $[2+2+2]$-product compared to the other triflate-based Lewis acid systems.

Table 11. Catalyst screening with phosphine ligands for the [4+2]-reaction, analysed by TLC after 48 h .

*Due to limited amount of material, only $20 \mathrm{~mol} \%$ of this ligand was used.

From these results (Table 11), one can deduce that the bidentate phosphine ligands seemed to perform better than the monodentate ones. In particular, ligands $\mathbf{3 7 4}$ and $\mathbf{3 7 5}$ seemed to be better in terms of clearly forming piperidenone $\mathbf{2 4 4}$ (as judged by TLC analysis). In contrast, the triflate-based catalyst always produced [2+2+2]product, whilst $\mathrm{CuCl}_{2}$ also formed the [2+2+2]-product when using certain phospine ligands. Interestingly, the $\mathrm{RuCl}_{3}$ catalyst gave a distinct new high $R_{f}$ spot by TLC
analysis, despite also giving the cleanest [4+2]-product spot. CuCl seemed to be the least active Lewis acid catalyst, and $\mathrm{InCl}_{3}$ seemed to give the most complex mixtures, as determined by TLC analysis.

On the whole, these reactions showed more spots by TLC analysis compared to using 2-ethyl-2-oxazoline as ligand. Hence, it was decided to take the most promising Lewis acids forward by scaling up the cleaner 2-ethyl-2-oxazoline methodology (Table 12). The Lewis acids taken forward were $\mathrm{CuCl}_{2}, \mathrm{CeCl}_{3}$ and $\mathrm{RuCl}_{3}$. For comparison, the reaction was also performed neat, with and without $3 \AA$ molecular sieves.

Table 12. Scaled up [4+2]-reactions (performed on a 1 mmol scale).

| Entry | Lewis Acid | After 24 h | After 48 h | Yield (\%) |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{CuCl}_{2}$ | A lot of imine and enone still present | Mostly enone and product, some imine present | 28 |
| 2 | $\mathrm{CeCl}_{3}$ | A lot of imine and enone still present | Mostly enone and product, some imine present | 49 |
| 3 | $\mathrm{RuCl}_{3}$ | No imine and little enone. Cleanest product. | Same as before | 44 |
| 4 | Neat with molecular sieves | Some imine, enone, diene and product present | Imine consumed: mainly product | 47 |
| 5 | Neat without Molecular sieves | Two prominent new spots along with enone, diene and imine present: no product | Two prominent new spots, along with a lot of enone, present: little product | - |

The slowest reaction seemed to be when $\mathrm{CuCl}_{2}$ was used (Table 12, entry 1), whilst the quickest reaction to go to completion seemed to be achieved with $\mathrm{RuCl}_{3}$ ( Table 12, entry 3). However, after purification by silica gel chromatography, the isolated product (Table 12 , entry 3 ) was black and clearly not clean, despite the ${ }^{1} \mathrm{H}$ NMR
showing a clean spectrum; a common problem with ruthenium systems and likely due to metal contamination.

When performing the reaction neat, the use of molecular sieves seemed to be essential because without them, the diene 4 quickly hydrolysed to the enone $\mathbf{3 5 0}$, and thus the diacetyl product 369 was formed instead of piperidenone 244 (Table 12, entry 5). When molecular sieves were used, a similar yield of $\mathbf{2 4 4}$ was obtained compared to when $\mathrm{CeCl}_{3}$ was used as the catalyst (Table 12, entries 4 and 2). These results suggest that it is essential to perform these reactions under inert conditions with the use of molecular sieves, and that many Lewis acids hinder the reaction instead of catalysing it.

Each of the reactions shown in Table 12 were purified directly after being quenched. This was important because if a significant amount of time lapsed after the quench and prior to the purification, then the unwanted [2+2+2]-product 369 would form. This was especially undesirable as the [2+2+2]-product 369 was challenging to separate from the desired piperidenone 244, and hence, lower isolated yields would be obtained (Table 13).

Table 13. [4+2]-reactions where the product $\mathbf{2 4 4}$ was not purified directly after quenching.

| Entry | Additive 1 <br> $(\mathrm{~mol} \%)$ | Additive 2 <br> $($ mol \%) | $[2+2+2]-$ <br> product 369 <br> observed | $[2+2+2]$-product <br> 369 observed <br> 24 hafter quench | $\mathbf{2 4 4}(\%)$ |

*After the compounds were quenched and concentrated in vacuo, they were left overnight (without molecular sieves) before purifying by silica gel chromatography. During this time, a noticeable amount of $[2+2+2]$-product was formed, which lowered the isolated yield of the [4+2]-product as they have almost identical $R_{f}$ values.
$\ddagger$ Despite being relatively clean directly after quenching, these reactions were not purified as they were contaminated by too much [2+2+2]-product 24 h after the quench.

From these studies, it was evident that in order to optimise the formation of the aza-Diels-Alder adduct 244, it was essential to perform these cycloadditions under anhydrous conditions. In addition, it is necessary for the diene $\mathbf{4}$ to be pure, with no enone 350 present. Otherwise, the unwanted diacetyl-piperidine ring 369 would be formed instead. Both these compounds arise through a different formal cycloaddition pathway: a [4+2]-cyclisation to give the aza-Diels-Alder adduct 244, and a $[2+2+2]$ cyclisation to give the diacetyl-piperidine 369 .

## $3.5 \quad[2+2+2]$-Cycloaddion Reaction

The unexpected observation of the formation of the $[2+2+2]$-cycloaddition product 369 was almost unprecedented, ${ }^{175}$ and therefore, this reaction required further investigation and optimisation. Initially, catalyst loading was investigated (Table 14), during which a new side-product $\mathbf{3 7 6}$ was observed. The side-product $\mathbf{3 7 6}$ was identified as the trimer because it was formed by the reaction from three equivalents of enone 350, followed by elimination of three equivalents of methanol.

Table 14. Investigating catalyst loadings in the formal $[2+2+2]$-cycloaddition reaction.

| Entry | Lewis Acid <br> $(\mathrm{mol} \%)$ | Yield of dihydropyridine <br> $\mathbf{3 6 9}(\%)$ | Yield of trimer <br> $\mathbf{3 7 6}(\%)$ |
| :---: | :---: | :---: | :---: |
| 1 | 0 | 0 | - |
| 2 | 5 | $<10$ | - |
| 3 | 10 | 61 | - |
| 4 | 20 | 48 | $<5^{*}$ |
| 5 | 100 | 0 | $>55$ |

* Conversion estimated from the crude ${ }^{1} \mathrm{H}$ NMR spectrum.

From these results (Table 14), one can deduce that the formation of trimer 376 was favoured over the formation of dihydropyridine 369 with increasing amounts of Lewis acid. However, with no Lewis acid present, no reaction occurred (Table 14, entry 1), which showed that the Lewis acid was important in terms of activating the enone $\mathbf{3 5 0}$. If the Lewis acid concentration was too low (5\%), very little activity was observed (Table 14, entry 2). Hence, a sensible compromise, where maximum amounts of dihydropyridine 369 was synthesised, with no trimer $\mathbf{3 7 6}$ being produced, was when $10 \mathrm{~mol} \%$ of the Lewis acid was used (Table 14, entry 3).

Figure 5. X-ray molecular structure of compound 376.

Due to the unusual aromatic downfield ${ }^{1} \mathrm{H}$ NMR peak of trimer 376 ( 8.7 ppm ), the structure of $\mathbf{3 7 6}$ was determined only after its crystal structure had been obtained (Figure 5). Examining the literature showed that other groups had isolated this compound when reacting 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ under acidic conditions. ${ }^{176}$ This transformation was confirmed by reacting enone $\mathbf{3 5 0}$ alone in the presence of a Lewis acid (Equation 31).

## Equation 31

When performing the reaction shown in Equation 31 in $\mathrm{CHCl}_{3}$ at room temperature for three days, purification by silica gel chromatography afforded the trimer $\mathbf{3 7 6}$ in $45 \%$ yield. The reaction shown in Equation 31 was also performed in $\mathrm{CDCl}_{3}$ in an NMR tube to monitor how long it took for enone $\mathbf{3 5 0}$ to completely convert into trimer 376. Within one day, 376 appeared. However, peaks corresponding to intermediates were also present. By the end of seven days, the signals in the ${ }^{1} \mathrm{H}$ NMR corresponding to 376 were more prominent compared to the intermediate peaks. After a month, the only peaks observed in the ${ }^{1} \mathrm{H}$ NMR spectrum were those corresponding
to the trimer 376, showing that the transformation was slow, although surprisingly efficient.

Having understood that catalyst concentration affects the formation of trimer $\mathbf{3 7 6}$ or otherwise, optimisation of dihydropyridine $\mathbf{3 6 9}$ was explored by examining the effect of catalyst, enone equivalents, drying agent, solvent and inert atmosphere. It was immediately apparent that different ranges of isolated yields were obtained depending on the purification process. Relatively low yields in the $20-40 \%$ range were generally observed when the reaction was purified by trituration (Table 15).

Table 15. Optimisation studies of the $[2+2+2]$-cycloaddition reaction, the product $\mathbf{3 6 9}$ being purified by trituration.

Note: P means that the flask was sealed with a septum, through which argon was pumped; F means the flask was flushed with argon before being sealed with a stopper; N means that the flask was sealed with a stopper without being flushed with argon; * means that the yield was not isolated, the amount being estimated from the crude ${ }^{1} \mathrm{H}$ NMR spectra.

Despite the low yields obtained, these results (Table 15) provided some added, useful information. For example, the use of $\mathrm{Sc}(\mathrm{OTf})_{3}, \mathrm{Yb}(\mathrm{OTf})_{3}$ or its hydrate as a catalyst gave little difference in yield (Table 15, entries $1,3,5$ ), with or without molecular sieves (Table 15, entries 3, 4). When comparing solvents, no significant difference was observed except when using methanol and acetonitrile, in which cases the yields tended to be lower (Table 15, entries 9-16). The concentration of the reaction mixture was also investigated (Table 15, entries 20-23) and it was observed by TLC analysis that the cleanest reaction was when the minimum amount of solvent was used (Table 15 , entry 22 ), sufficient only for complete solution of reagents.

Higher yields of $\mathbf{3 6 9}$ were typically obtained when the reaction mixture was purified by silica gel chromatography using EtOAc as eluent (Table 16, entries 1-3). This purification procedure was subsequently optimised by including $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ in the eluent mixture (4:1, EtOAc: $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) to help with the solubility of $\mathbf{3 6 9}$ (Table 16, entries 610).

These results (Table 16) showed the importance of optimising the purification procedure in order to maximise yields. The Lewis acids that afforded the highest yields were $\mathrm{Fe}(\mathrm{OTf})_{2}$ and $\mathrm{Ga}(\mathrm{OTf})_{3}$ (Table 16, entries 7, 8), whilst the chiral Lewis acid $\mathrm{Eu}(\mathrm{hfc})_{3}$ seemed to be inactive, even at higher temperatures (Table 16, entry 4, 5). Overall, the highest yields obtained of pure product 369 were a very satisfactory $88 \%$ (Table 16, entries 7-8). Considering the very low yields obtained initially and the complexity of the reactions, this shows that the reaction could be very usefully optimised. In addition, three new bonds are formed in sequence, showing that each one can be formed with greater than $96 \%$ efficiency.

Table 16. Optimisation studies of the $[2+2+2]$ cycloaddition reaction, the product $\mathbf{3 6 9}$ being purified by silica gel chromatography.

| Entry | Lewis acid | Purification Eluent | $\mathbf{3 6 9 ( \% )}$ |

| 5 | $\mathrm{Eu}(\mathrm{hfc})_{3}\left(60{ }^{\circ} \mathrm{C}\right)$ | - | - |
| 6 | $\mathrm{Sc}(\mathrm{OTf})_{3}$ | $4: 1, \mathrm{EtOAc}: \mathrm{CH}_{2} \mathrm{Cl}_{2}$ | 82 |
| 7 | $(+\mathrm{Pybox} 10 \mathrm{~mol} \%)$ |  |  |
| 8 | $\mathrm{Fe}(\mathrm{OTf})_{2}$ | $4: 1, \mathrm{EtOAc}: \mathrm{CH}_{2} \mathrm{Cl}_{2}$ | 88 |
| 9 | $\mathrm{Ga}(\mathrm{OTf})_{3}$ | $4: 1, \mathrm{EtOAc}: \mathrm{CH}_{2} \mathrm{Cl}_{2}$ | 88 |
| 10 | $\mathrm{Yb}(\mathrm{OTf})_{3}$ | $4: 1, \mathrm{EtOAc}: \mathrm{CH}_{2} \mathrm{Cl}_{2}$ | 87 |

Similar results were observed when using enone synthons of $\mathbf{3 5 0}$, such as the alkyne 3-butyn-2-one 377 (Equation 32), demonstrating that the interaction of the corresponding ynone might be involved in the reaction.

Equation 32

Compound $\mathbf{3 6 9}$ is a very polar, yellow solid that is extremely long wave (LW) UV active. As determined by crystallography experiments, $\mathbf{3 6 9}$ is highly delocalised between the nitrogen and the first conjugated acetyl group, with both acetyl groups being in the same plane.

X-ray diffraction experiments (Table 17) were carried out on a 3-circle Bruker diffractometer with a SMART 6000 CCD area detector, using graphitemonochromated Mo- $K_{a}$ radiation ( $\bar{\lambda}=0.71073 \AA$ ) and a Cryostream 700 (Oxford

Cryosystems) open-flow $\mathrm{N}_{2}$ cryostat. The structure was solved by direct methods and refined by full-matrix least squares against $F^{2}$ of all reflections, using SHELXTL $6.14^{177}$ and OLEX2 ${ }^{178}$ software. Dr. Andrei Batsanov performed both the X-ray diffraction experiments and the DFT calculations.

The molecular structure of $\mathbf{3 6 9}$ is shown in Figure 6; bond distances are listed in Table 18. Ring $A$ adopts a sofa conformation, the $\mathrm{C}(5)$ atom is displaced by $0.37 \AA$ from the mean plane of the remaining five atoms (which are coplanar with the mean deviation of $0.03 \AA$ ). The latter plane forms dihedral angles of $78.0^{\circ}$ with the arene
ring $B, 3.0^{\circ}$ and $14.2^{\circ}$ with the acyl groups bonded to $\mathrm{C}(2)$ and $\mathrm{C}(4)$. The nitrogen atom has an almost planar geometry (the sum of bond angles $358.1^{\circ}$ ) and there is a significant $\pi$-delocalisation along the (nearly planar) $\mathrm{NC}(1) \mathrm{C}(2) \mathrm{C}(14) \mathrm{O}(1)$ path. Thus, the $\mathrm{N}-\mathrm{C}(1)$ and $\mathrm{C}(2)-\mathrm{C}(14)$ bonds are shorter than the standard single bonds (1.355 and $1.464 \AA$, respectively) and $\mathrm{C}(1)=\mathrm{C}(2)$ and $\mathrm{C}(14)=\mathrm{O}(1)$ are longer than the standard double bonds ( 1.340 and $1.222 \AA$ ) in similar moieties. ${ }^{179}$

Figure 6. X-ray molecular structure of compound 369.

The DFT calculation failed to reproduce this delocalisation fully, although other bond distances are in reasonable agreement with the observations (Table 18) and the conformation of ring $A$ is identical within experimental error. The angles between the $\mathrm{NC}(1) \mathrm{C}(2) \mathrm{C}(3) \mathrm{C}(4)$ plane and the two acyl groups ( $2.0^{\circ}$ and $15.2^{\circ}$ ) reproduce the observed conformation accurately; the angle of the former with ring $B\left(69.8^{\circ}\right)$ is smaller than the observed by $8^{\circ}$, although this difference can be due to crystal packing effects.

The crystal structure of 376, studied at 120 K (Figure 7), is essentially the same as determined earlier by X-ray ${ }^{180}$ and neutron diffraction ${ }^{181}$ at room temperature. This molecule 376 has a nearly planar conformation: the acetyl substituents in positions 1, 3 and 5 are twisted with respect to the benzene ring plane by $6.6^{\circ}, 7.7^{\circ}$ and $9.2^{\circ}$, respectively. Molecules in crystal are stacked in slightly puckered layers (Figure 8). At room temperature, the $\mathrm{O}(1)$ atom showed large thermal vibrations in the direction perpendicular to the molecular plane, much larger than the other two oxygen atoms. Interestingly, this situation persists at low temperature (attempts to rationalise it as
static disorder were unsuccessful). It is probably due to the crystal packing allowing more leeway for $\mathrm{O}(1)$ than for $\mathrm{O}(2)$ and $\mathrm{O}(3)$. Thus, the shortest inter-layer $\mathrm{O} \ldots \mathrm{C}$ distances on either side of the molecular plane, equal 3.65 and $3.83 \AA$ for $\mathrm{O}(1), 3.41$ and $3.57 \AA$ for $\mathrm{O}(2), 3.21$ and $3.30 \AA$ for $\mathrm{O}(3)$.

Figure 7. X-ray molecular structure of compound 376.

Figure 8. Crystal packing of $\mathbf{3 7 6}$.

The mechanism for the formal $[2+2+2]$-cycloaddition reaction has been proposed below (Scheme 59). It was thought that the Lewis acid could initially coordinate to the carbonyl oxygen of the enone (378), which would in turn make it sufficiently electrophilic for a second enone $\mathbf{3 5 0}$ to perform a conjugate addition in order to form the first enolate-oxonium intermediate 379. At high Lewis acid concentrations, this enolate-oxonium intermediate $\mathbf{3 7 9}$ would most likely interact with a third Lewis-acid activated enone molecule $\mathbf{3 7 8}$ in order to undergo a second conjugate addition to form 381, followed by cyclisation (to 382) and elimination of methanol to afford the trimer 376. However, with lower Lewis acid concentrations, it was believed that there would be less Lewis acid activated enone and hence, the initial enolate-oxonium intermediate 379 would more likely interact and cyclise with the imine 243, most probably through a step-wise Mannich-Michael pathway, and then eliminate methanol in order to form the dihydropyridone $\mathbf{3 6 9}$ (Scheme 59).

Scheme 59. Proposed mechanisms for the formation of the dihydropyridine 369 and the trimer 376.

In order to test the scope of the formal [2+2+2]-cycloaddition reaction, enone $\mathbf{3 5 0}$ was reacted with different cyclic imines $\mathbf{3 8 3}$ with the aim of forming different dihydropyridines 384 (Table 20). However, isolation of other desired dihydropyridines $\mathbf{3 8 4}$ proved challenging in both cases.

Table 20. [2+2+2]-Cycloaddition attempts between cyclic imines $\mathbf{3 3 8 3}$ and enone 350.

| Entry | Imine | Cycloadduct obtained? |
| :---: | :---: | :---: |
| 1 | (mixture of products) |  |

To summarise, in all of the sets of reactions relating to the formal $[2+2+2]-$ cycloadditions, it was observed that the Lewis acid concentration was important: too low and no reaction occurred; too high and the trimer $\mathbf{3 7 6}$ formation would compete
with dihydropyridine 369 formation. Optimising the purification procedure was important to maximise on yield, though this could be achieved in nearly $90 \%$ yield. These dihydropyridines were only obtained when specifically using 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ or similar synthons. However, this formal [2+2+2]-cycloaddition reaction still needs to be tested on a larger array of cyclic imines to see how general it is. To date, no other imines have reacted equally successfully to $\mathbf{2 4 3}$.

### 3.6 Formal [1+2+1+2]-Cycloaddition Reactions

It had been observed that if an aza-Diels-Alder reaction between a cyclic imine and an enone with a leaving group on the $\beta$-position, such as 4 -methoxy-3-buten- 2 -one, is carried out, then a formal [2+2+2]-cycloaddition would take place to afford diacetyldihydropyridine derivatives, as opposed to a formal [4+2]-cycloaddition to form dihydropyridones. In order to further test the scope of the formal [2+2+2]cycloaddition reaction, the use of acyclic imines was explored.

Initially, acyclic imine 324 was reacted with two equivalents of enone $\mathbf{3 5 0}$ in the presence of $20 \mathrm{~mol} \% \mathrm{Yb}(\mathrm{OTf})_{3}$ in the expectation of forming the diacetyl product 385. However, after purification by silica gel chromatography, the isomer $\mathbf{3 8 6}$ and the [4+2]-cycloaddition product 362 were isolated in $20 \%$ and $2 \%$ yields respectively (Equation 33). No [2+2+2]-product $\mathbf{3 8 5}$ was observed.

Equation 33

Dihydropiperidine 386 was an interesting and unexpected product because it was formed by a formal [1+2+1+2]-cyclisation pathway, i.e. via a four-component reaction. Evidence for the isomer obtained came from the ${ }^{1} \mathrm{H}$ NMR, which showed the two acetyl methyl groups as one singlet ( $\delta=2.15 \mathrm{ppm}$ ), with an integral of six protons indicating the symmetric nature of the structure. Compound $\mathbf{3 8 5}$ however, would show two distinct singlets. The structure of compound $\mathbf{3 8 6}$ was also confirmed by single crystal X-ray structure (Figure 9).

Figure 9. X-ray molecular structure of compound 386.

In light of this novel result, a selection of acyclic imines 11 were reacted with 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ at room temperature with a lower catalyst loading ( $10 \mathrm{~mol} \%$ ), in order to determine the scope of this reaction with different acyclic imines 11. As well as accessing a number of new adducts 387, a number of unexpected compounds were also formed, as outlined in Table 21.

These reactions (Table 21) were generally more complex than expected and after purification by silica gel chromatography, many compounds were isolated. It was challenging to isolate them, and those that were isolated (Table 21, entries 1-2) were only retrieved in low yields (20-31\%). Indeed, many of the crude ${ }^{1} \mathrm{H}$ NMRs showed mainly starting materials, which could explain some of the low yields. However, from this set of reactions, it was obvious that the imine $\mathbf{1 1}$ was hydrolysing to the amine and aldehyde components and reacting separately. This showed that in order to form compounds such as $\mathbf{3 8 5}$, it was important to have imines that do not easily hydrolyse, such as cyclic systems.

Table 21. Reactions between acyclic imines 11 and enone 350.
Entry

In addition, main side-products that were observed were the Michael adducts $\mathbf{3 8 9}$ and 358, resulting from reaction between the amine and enone 350 (Table 21, entries 3 and 5). This suggested that the mechanism for the formation of the $[1+2+1+2]-$
adducts could involve formation of a vinylogous amide intermediate; a hypothesis that could be readily tested.

The alkene conformation of the Michael adducts $\mathbf{3 8 9}$ and $\mathbf{3 5 8}$ were determined to be cis due to the low alkene and high amine proton J coupling constants ( $J=7$ and 12 Hz , respectively), values that are expected for cis vinylogous amides. ${ }^{182}$ In addition, the NH signal on the ${ }^{1} \mathrm{H}$ NMR ( 10 ppm ) was less shielded than is expected for a normal NH peak (ca. 6.5 ppm ). This suggests there is an intramolecular H-bond to the carbonyl oxygen, which is in agreement with the literature. ${ }^{183}$

In Table 21, entry 5, there was an example where use of methanol inhibited piperidine product formation compared with chloroform, which agrees with the results observed for the $[2+2+2]$-cycloaddition reactions (Table 15). This could be due to the formation of side-product $\mathbf{3 9 0}$ resulting from methanolysis of the vinyl ether of 350, or stalling of the rest of the cascade reaction due to intermediate H -bonding in the polar, protic solvent.

A TLC spot corresponding to compound 358 (Table 21, entry 5) was also observed in the reaction mixture of entry 1 . However, this compound was not isolated (in entry 1) since it was not present in sufficiently high concentration according to TLC.

Considering that the imine $\mathbf{3 2 4}$ almost certainly had to be hydrolysed to the amine and aldehyde components in order to access isomer 386 through a formal $[1+2+2+1]-$ cycloaddition pathway, it was realised that this may have been due to the presence of water in the reaction mixture. Hence, the reaction was attempted under anhydrous conditions (argon, $3 \AA$ molecular sieves, dried solvents and dried reagents). Despite these precautions, TLC analysis confirmed that isomer 386 was still being formed, suggesting that some water was still present in the reaction mixture. It was thought that the Lewis acid $\left[\mathrm{Sc}(\mathrm{OTf})_{3}\right]$ might be too hygroscopic to completely dry and indeed, other groups have gone to extreme measures in vain attempts to completely remove all water coordinated to triflate-based Lewis acids. ${ }^{184}$ Similar results were observed (where isomer 386 was preferentially formed over 385) when using $\mathrm{In}(\mathrm{OTf})_{3}, \mathrm{Yb}(\mathrm{OTf})_{3}, \mathrm{TiCl}_{4}, \mathrm{ZnCl}_{2}$ etherate and $\mathrm{BF}_{3}$ as the catalyst (Equation 34).

## Equation 34

A closer investigation involving the reaction of one equivalent of both amine $\mathbf{8 6}$ and aldehyde $\mathbf{8}$ with two equivalents of 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ in the presence of a Lewis acid formed the corresponding diacetyl dihydropyridines $\mathbf{3 8 7}$ (Table 22) with low to high efficiency, revealing the generality of the reaction.

In terms of use of different aldehydes (Table 22), higher yields were generally obtained with aromatic aldehydes, whereas, for amines, lower yields were obtained with either less nucleophilic amines (such as aniline, Table 22, entries 6 and 7) or more bulky amines (such as tert-butylamine, Table 22, entries 13 and 14). In these cases, the reactions tended to stall at the initial Michael-addition step to form the vinylogous amides, i.e. resulting in the isolation of compounds 397, 402, 407 and 389. This could generally be overcome to some extent by heating the reaction to $60{ }^{\circ} \mathrm{C}$ (Table 22, entry 14). However, this also resulted in the formation of the doubly vinylogous amide product 409 being the major product.

The highest yield was obtained when using benzylamine 391 and $p$-nitrobenzaldehyde 354 (Table 22, entry 1). Interestingly, when the role of the solvent was examined by running the reaction in different solvents and monitoring by $\mathrm{TLC}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$ appeared to provide the cleanest reaction mixtures after 48 h compared with other solvents. The preferred order of reactivity was $\mathrm{CH}_{2} \mathrm{Cl}_{2}>\mathrm{THF}>\mathrm{EtOAc}>\mathrm{MeOH}>$ toluene. Many of the products were also crystalline and hence, their structures were confirmed by single crystal X-ray diffraction studies (Figure 10).

Figure 10. X-ray molecular structures of diacetyl dihydropyridines.

The biological activity of the compounds shown in Figure 10 were explored by Dr. Paul Yeo, along with that of the $[2+2+2]$-cycloaddition product $\mathbf{3 6 9}$. They were tested against the cell line A549 infected with the Respiratory Syncytial Virus (RSV), which causes respiratory disease. The main individuals at risk from this virus are infants less than six months of age, with RSV being the major cause of hospitalisation for severe respiratory disease in this age group. After this, 'flu' becomes the major cause of respiratory disease towards individuals until they reach 70+ years of age, after which RSV becomes a major cause of mortality due to respiratory disease (although no one knows why this is). For most people, about one third of the events we normally attribute as colds is due to RSV, so finding a cure also has an economic impact due to days taken off work. No effective vaccine or drug treatment is currently available and the potential of a new drug against RSV would be worth up to $£ 2$ billion a year. When the compounds were tested between the $100 \mu \mathrm{M}$ and 1 nM level, these alkaloids were found to be very insoluble when added to the aqueous solution. However, no cells were observed, suggesting these compounds could be very potent on this cell line and that future tests should be done with solutions below the 1 nM level. In addition, it was noted that these alkaloids should be tested again to obtain solubility levels.

It was also interesting to note that the isolated MeOH adduct $\mathbf{4 1 1}$ slowly converted to the more thermodynamically favourable dihydropyridine $\mathbf{4 1 0}$ when left in solution (Equation 35). This suggests that probably the last step in the mechanism involves elimination of methanol. This step would be slower when using relatively less nucleophilic amines, such as aniline $\mathbf{9 0}$ and $p$-anisidine 120.

Equation 35

In order to probe the mechanism of the formal $[1+2+1+2]$-cycloaddition reaction further, the ${ }^{1} \mathrm{H}$ NMR studies outlined in Table 23 were carried out. This involved attempts to follow each stage of the reaction by varying the ratio of reagents and orders of addition, followed by NMR examination. The results are summarised in Table 23.

Table 23. Mechanistic studies towards the [1+2+1+2]-cycloaddition reaction.

* Conversions estimated with respect to the amount of MeOH produced in the reaction, by 1 H NMR integration.

It was possible to be reasonably certain that the initial intermediate formed in these formal $[1+2+1+2]$-cycloaddition reactions was the vinylogous amide 397, for several reasons:

1) this intermediate was isolated several times in the reactions in Table 22, i.e. entries 4, 7, 13 and 15 ;
2) reaction of enone $\mathbf{3 5 0}$ (2 Equiv.) with amine $\mathbf{3 9 1}$ (1 Equiv.) in the absence of aldehyde $\mathbf{3 5 4}$ gave the vinylogous amide 397 and unreacted enone $\mathbf{3 5 0}$ (Table 23, entry 1), and subsequent addition of aldehyde 354 gave rapid conversion to the cycloadduct 392 (ca. 60\%);
3) if the enone $\mathbf{3 5 0}$ (2 Equiv.) was reacted with the amine $\mathbf{3 9 1}$ (2 Equiv.), only the intermediate vinylogous amide 397 was formed. Subsequent addition of the aldehyde $\mathbf{3 5 4}$ (1 Equiv.) resulted in the less efficient formation of the dihydropyridine 392 (32\%) (Table 23, entry 2);
4) the vinylogous amide 397 was formed just as efficiently in the absence of the Lewis acid (Table 23, entry 3) and subsequent addition of aldehyde 354 and a Lewis acid provided the cycloadduct $\mathbf{3 9 2}$ with a similarly low conversion as in entry 2 (32\%) (Table 23);
5) the dihydropyridine 392 was formed most efficiently and cleanly by reaction of enone $\mathbf{3 5 0}$ (1 Equiv.), amine 391 (1 Equiv.) and aldehyde 354 (1 Equiv.), followed by the addition of another equivalent of enone $\mathbf{3 5 0}$ (Table 23, entry 4);
6) Similarly high conversion rates ( $98 \%$ ) to the dihydropyridine 392 were obtained when the vinylogous amide 397 (1 Equiv.) was pre-formed in situ prior to addition of the aldehyde 354 (1 Equiv.) (Table 23, entry 5), suggesting this intermediate 397 formed quickly and selectively, regardless of the other reagents in the reaction mixture.

By taking all of the results in Table 23 into account, an array of potential mechanisms (Scheme 60) could be considered and some discarded. Hence, enone $\mathbf{3 5 0}$ and amine $\mathbf{8 6}$ must first react together to form vinylogous amide 412. This can then react via pathways A, B or C to produce the final product $\mathbf{3 8 7}$. However, when path C was probed, where the vinylogous amide 412 reacts initially with the enone $\mathbf{3 5 0}$ followed by the aldehyde ( $98 \%$ ) 8 (Scheme 60), a moderate conversion of $60 \%$ was obtained (Table 23, entry 1). When path B was probed, where two vinylogous amides 412 react with one aldehyde 8 to form a doubly vinylogous amide 415 prior to cyclisation (Scheme 60), a low conversion of 32-33\% was obtained (Table 23, entries 2 and 3). However, when path A was probed, where the vinylogous amide 412 initially reacts with the aldehyde $\mathbf{8}$ followed by the enone $\mathbf{3 5 0}$ (Scheme 60), high conversion to 387 ( $97-98 \%$ ) was obtained (Table 23, entries 4 and 5), suggesting the order of events is as outlined in this pathway. This differs from the related process reported by Inouye, ${ }^{186}$ who claimed that two equivalents of a vinylogous amide reacted with one equivalent of aldehyde.

413

416

414

415
387

Scheme 60. Probing the mechanistic pathway of the formal $[1+2+1+2]$-cycloaddition.

Hence, these results strongly suggest that the mechanistic order of events is as outlined in Scheme 61, i.e. that intermediate $\mathbf{4 1 2}$ formed quickly and reacted with an aldehyde 8 to give species 417 assisted by the Lewis acid. It is believed that from this intermediate 417, it is likely that two possible pathways may operate. Either a DielsAlder cycloaddition pathway can occur via scandium-assisted elimination to derive electron deficient aza-diene 418, which could undergo inverse electron demand Diels-Alder cycloaddition with further enone 350 to derive 419 . This can then eliminate; or, the enamine intermediate 417 could protonate (to give 413) and react with the enone $\mathbf{3 5 0}$ in a Lewis-acid assisted Michael addition process to derive $\mathbf{4 2 0}$. This species then requires cyclisation, presumably via an enolate equivalent cyclising onto an unsaturated iminium ion such as 421, to derive the same intermediate 419, from which methanol elimination can occur to afford the product 387.

Scheme 61. Proposed mechanism for the formal $[1+2+1+2]$ cycloaddition reaction.

Further evidence for the process outlined in Scheme 61 came from the isolation of the MeOH adduct 400 in $27 \%$ from the reaction involving aniline 90 and p-nitrobenzaldehyde 354 (see Table 22, entry 6).

Figure 11. X-ray molecular structure of the MeOH adduct 400.

Isolation of compound 400 is a clear example of the importance of species 419 in Scheme 61. Single crystal X-ray analysis clearly revealed that this compound $\mathbf{4 0 0}$ was as shown in Figure 11 and must correspond to the last intermediate before $\beta$ elimination occurs, to give the dihydropyridine 387, as outlined in Scheme 61.

It is interesting to note that similar dihydropyridine reactions using vinylogous amides 422 (instead of enones with a leaving group on the $\beta$-position) are thought to go through doubly vinylogous intermediate 424 (Equation 36), ${ }^{188}$ similar to the one shown in Path B of Scheme 60. This suggests that this reaction could be going through a different mechanistic pathway, i.e. via a doubly vinylogous amide 424. Liu et al. have demonstrated that this particular reaction needs to be heated to $80-90^{\circ} \mathrm{C}$ for the reaction to go through this pathway (Equation 36). ${ }^{188}$

Equation 36

The need for heating in order for the cyclisation to occur for systems involving intermediate 424 (Equation 36) can be understood from examination of the obtained X-ray crystal structure of the doubly vinylogous compound 409 (Figure 12). As explained in Table 22, entry 14, the dihydropyridine product 408 was only obtained (in low yield) after heating the mixture at $60^{\circ} \mathrm{C}$; only the vinylogous amide 407 was obtained when the reaction was performed at room temperature (Table 22, entry 13). The major product from heating at $60^{\circ} \mathrm{C}$ was the doubly vinylogous compound 409 , showing that heat was needed in order to form these compounds. However, X-ray crystal structure of $\mathbf{4 0 9}$ showed this compound was particularly stable due to two sets
of intramolecular H -bonds (Figure 12). Hence, it was presumed that additional energy ( $80-90^{\circ} \mathrm{C}$ ) would be needed in order for the doubly vinylogous amide 424 to break these H -bonds and cyclise. This could explain why such doubly vinylogous amides 424 were not observed when the reaction was performed at room temperature, and why high temperatures of $80-90^{\circ} \mathrm{C}$ were necessary when using vinylogous amides 422, where the mechanism is proposed to go through the doubly vinylogous intermediate 424 (Equation 36).

Figure 12. X-ray molecular structure of the double vinylogous amide 409.

Referring back to the attempts where an imine $\mathbf{1 1}$ was reacted with the enone $\mathbf{3 5 0}$ under anhydrous conditions (Equation 34), it was presumed that the imine was being hydrolysed to its amine and aldehyde components. However, if it was believed that the system was completely free from water, then one cannot ignore a different initial mechanism whereby the imine could react with a Lewis acid activated enone compound. The subsequent elimination of methoxide ion could hydrolyse the imine 425, and in turn lead to the formation of intermediate 429. Subsequent $\beta$-elimination of the MeOH would afford the diene 418 (Scheme 62). As shown in Scheme 61, diene

418 could undergo a formal aza-Diels-Alder reaction with a second enone $\mathbf{3 5 0}$ in order to afford the dihydropyridine 387 , after elimination of MeOH .

Scheme 62. Alternative mechanism to intermediate 418 from imine 11.

Understanding that the reaction intermediate $\mathbf{4 1 8}$ could potentially undergo an aza-Diels-Alder reaction with a second enone in order to afford a piperidine of type 419, the reaction scope with different enones $\mathbf{1 8 3}$ to form substituted piperidines $\mathbf{4 3 0}$ was investigated (Table 24). In this case, the initial enone 350, amine 391 and aldehyde 354 were allowed to react in the presence of the Lewis acid prior to addition of the second enone 183. The enones investigated were methyl vinyl ketone (Table 24, entry 1) and 4-phenyl-3-buten-2-one (Table 24, entry 2). However, on each occasion, TLC analysis mainly showed the presence of dihydropyridine $\mathbf{4 0 0}$ and unreacted starting materials; there was no clear evidence that piperidines $\mathbf{4 3 0}$ were being formed.

Table 24. The use of different enones in the [1+2+1+2]-reaction.

| Entry | R | Cycloadduct $\mathbf{4 3 0}$ obtained? |
| :---: | :---: | :---: |
| 1 | H | No |
| 2 | Ph | No |

In summary, it has been deduced that under these reaction conditions (Table 21), imines hydrolyse to amine and aldehyde components, after which the amine can react with a methoxy enone to form a vinylogous amide. In the presence of a Lewis acid, this can then react with an aldehyde and a second methoxy enone to form a new dihydropyridine. The reaction goes through a formal [1+2+1+2]-cycloaddition pathway in a novel one-pot, four-component cyclisation reaction. The mechanism has not been fully determined, however, evidence for these studies involves the isolation of intermediates within the reaction mixture, as well as high conversion when the reagents were reacted in the proposed order.

### 3.7 Formal [4+2]-Cycloadditions Using Enones

It was observed that when cyclic imines were reacted with 4-methoxy-3-buten-2-one, a [2+2+2]-formal cycloaddition occurred to form diacetyl-dihydropyridines. If acyclic imines were used, then the reaction went through a formal $[1+2+1+2]$-cyclisation pathway forming a different class of dihydropyridine. ${ }^{189}$ Hence, it was realised that cyclic imines that do not easily hydrolyse are essential for a formal [2+2+2]cyclisation pathway to proceed.

In order to determine the scope of the formal [2+2+2]-cyclisation reaction by using enones 183 that do not contain a leaving group (LG) on the $\beta$-position, the cyclic imine $\mathbf{2 4 3}$ was reacted with 2 equivalents of two different enones: 4-phenyl-3-buten-2-one 348 and methyl vinyl ketone 164 (Table 25).

Table 25. Reaction of an enone 183 with imine 243 , where $R \neq L G$.
Entry $\quad$ Enone $\quad$ Lewis acid $\quad$ Time

When using 4-phenyl-3-buten-2-one $\mathbf{3 4 8}$ (Table 25, entry 1), the aza-Diels-Alder product 431 was obtained in moderate yield and seemingly a single diastereoisomer. It was found that this reaction was slow ( 72 h ) and that the use of excess enone 348 made identification and purification by silica gel chromatography challenging because the product $\mathbf{4 3 1}$ and enone $\mathbf{3 4 8}$ had almost identical $R_{f}$ values. Hence, the product $\mathbf{4 3 1}$ was only isolated analytically pure after purification using reverse phase chromatography. The stereochemistry of this product was determined to be as shown in Table 25, entry 1, with both the methine protons presumed axial, as shown by a strong NOE between them, suggesting 431 exists as shown in Figure 13. It was thought that in order to form this product, the reaction would probably have gone through a Mannich-Michael pathway (vide supra).

Figure 13. Proposed conformation of compound 431.

When using methyl vinyl ketone 165 as the enone (Table 25, entry 3), the aza-DielsAlder product 433 was obtained in low yields within 24 hours. However, the isoquinolium salt 432 was predominantly obtained; this structure was attributed in part due to a low field $\mathrm{N}=\mathrm{CH}$ resonance of 9.20 ppm in the ${ }^{1} \mathrm{H}$ NMR spectrum, with the connectivity confirmed by analysing the HSQC and HMBC spectra. This implied that the initial attack of the imine $\mathbf{2 4 3}$ on the enone $\mathbf{1 8 3}$ was likely to have been via a Michael-type reaction when using methyl vinyl ketone as the enone, followed by a Mannich cyclisation to form the aza-Diels-Alder product 433.

In order to further confirm the structure of the isoquinolium salt 432, the reaction between imine 243 and methyl vinyl ketone 164 was performed in the presence of trifluoromethanesulfonic (triflic) acid in an attempt to compare the salt formed with the isoquinolium salt 432. However, the crude ${ }^{1} \mathrm{H}$ NMR indicated that instead of forming the isoquinolium salt 432, the salt 434 had been formed instead (Equation 37). Considering triflic acid is a strong superacid, it is believed that protonation takes
place because the acidic proton from triflic acid is more electrophilic (harder) than the methyl vinyl ketone 164.

## Equation 37

Evidence for the formation of $\mathbf{4 3 2}$ includes the observance in the ${ }^{1} \mathrm{H}$ NMR of: 1) the imine $H a$ peak was split into a doublet; 2) the $H b$ peak was a multiplet as opposed to being a clear t ; 3) a br s peak that would account for the NH [ ${ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ) $\delta 8.54(\mathrm{~d}, J=8.5 \mathrm{~Hz}, 1 \mathrm{H}, H a), 8.11(\mathrm{br} \mathrm{s}, 1 \mathrm{H} N H), 7.84(\mathrm{~d}, J=7.5 \mathrm{~Hz}, 1 \mathrm{H}$, $H g), 7.78(\mathrm{t}, J=7.5 \mathrm{~Hz}, 1 \mathrm{H}, H f), 7.53(\mathrm{t}, J=7.5 \mathrm{~Hz}, 1 \mathrm{H}, H e), 7.40,(\mathrm{~d}, J=7.5 \mathrm{~Hz}$, $1 \mathrm{H}, H d), 4.11-4.05(\mathrm{~m}, 2 \mathrm{H}, H b), 3.24(\mathrm{t}, J=8.2 \mathrm{~Hz}, 2 \mathrm{H}, H c)]$.

Considering that the methyl vinyl ketone $\mathbf{1 6 4}$ had to be acting as a Michael acceptor for the formation of isoquinolium salt 432, the reaction between imine $\mathbf{2 4 3}$ and methyl vinyl ketone 164 was explored further using different oxy-philic Lewis acid catalysts. These reactions were screened using LCMS, with the crude reaction mixtures of the more promising Lewis acids being subsequently analysed by ${ }^{1} \mathrm{H}$ NMR (Table 26).

From the screening studies (Table 26), it was found that the formation of the isoquinolium salt 432 was most favourable when using $\operatorname{In}(\mathrm{OTf})_{3}$ as catalyst (Table 26, entry 7).

Table 26. Lewis acid screening.

| Entry | Lewis Acid | Was product 432/433 observed by LCMS? | Was the reaction clean enough to take further? | Crude ${ }^{1}$ H NMR result |
| :---: | :---: | :---: | :---: | :---: |
| 1 | $\mathrm{AuCl}_{3}$ | No | No | - |
| 2 | $\mathrm{HAuCl} 4_{4} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ | Yes | Yes | Complex spectrum |
| 3 | $\mathrm{Ag}(\mathrm{OTf})_{3}$ | Yes | No | - |
| 4 | $\mathrm{Cu}(\mathrm{OTf})_{3}$ | Yes | No | - |
| 5 | $\mathrm{Eu}(\mathrm{hfc})_{3}$ | Yes | No | - |
| 6 | $\mathrm{La}(\mathrm{OTf})_{3}$ | Yes | Yes | Both 432 and 433 observed |
| 7 | $\operatorname{In}(\mathrm{OTf})_{3}$ | Yes | Yes | 432 cleanly observed |
| 8 | $\mathrm{Sc}(\mathrm{OTf})_{3}$ | Yes | Yes | Complex spectrum, difficult to see either $\mathbf{4 3 2}$ or $\mathbf{4 3 3}$ |

The isoquinolium salt 432 could probably subsequently be cyclised in situ by treatment with base, including NaOH , diisopropylamine and L-proline (Table 27). Indeed, simultaneously using catalytic amounts of both $\operatorname{In}(\mathrm{OTf})_{3}$ and L-proline afforded the aza-Diels-Alder product 433 (Table 27, entry 4), albeit in racemic form. Reacting imine 243 and methyl vinyl ketone $\mathbf{1 6 4}$ in the presence of L-proline with no $\operatorname{In}(\mathrm{OTf})_{3}$ afforded negligible amounts of product 433, as determined by crude ${ }^{1} \mathrm{H}$ NMR after 72 h ; mostly starting material remained unreacted under these conditions (Table 27, entry 5). A similar transformation was found in the literature and the procedure followed, ${ }^{190}$ whereby mixing imine 243 and methyl vinyl ketone $\mathbf{1 6 4}$ in acid (such as HCl ), followed by a base quench (such as $\mathrm{NH}_{4} \mathrm{OH}$ ) afforded the aza-Diels-Alder product 433 in good yield of $74 \%$ (Table 27, entry 6). Interestingly, when a reducing agent such as $\mathrm{NaBH}(\mathrm{OAc})_{3}$ was used (Conditions B), the product $\mathbf{4 3 3}$ was obtained as the major product after basic work up (Table 27, entry 2).

Table 27. Synthesis of the piperidinone 433.

| Entry | Solvent | Conditions A <br> $(24 \mathrm{~h})$ | Conditions B <br> $(24 \mathrm{~h})$ | Yield 433 <br> $(\%)$ | ee (\%) |
| :---: | :---: | :---: | :---: | :---: | :---: |

${ }^{*}$ Values estimated from crude ${ }^{1} \mathrm{H}$ NMR

Considering that the cycloadduct $\mathbf{4 3 3}$ was only being synthesised in moderate yields, the different species in the reaction mixture were monitored in an attempt to determine why this was (Table 28).

From these reactions (Table 28), it was observed that the use of $\mathrm{NaBH}(\mathrm{OAc})_{3}$ reduced the isoquinolium salt $\mathbf{4 3 2}$ to $\mathbf{4 3 5}$, and hence, gave lower yields of cycloadduct 433 (Table 28, entries 2, 10). It was also observed that both NaOAc and $\mathrm{NaBH}(\mathrm{OAc})_{3}$ acted as a mild base to cyclise 432 to 433 (Table 28, entry 3). However, NaOH base was needed for higher conversion of $\mathbf{4 3 2}$ to $\mathbf{4 3 3}$ (Table 28, cf. entry 3 with entries 4-5, 10).

Table 28. Further studies into the reaction between imine 433 and methyl vinyl ketone 164.

In terms of the solvents used, the preferred order in terms of achieving the cycloadduct 433 most efficiently was $\mathrm{CH}_{2} \mathrm{Cl}_{2}>\mathrm{EtOAc} / \mathrm{MeOH} / \mathrm{MeCN}>$ THF (Table 28, entries 1, 6-9). Similarly, the order of Lewis acid reactivity towards preferred formation of the cycloadduct 433 was $\operatorname{In}(\mathrm{OTf})_{3}>\mathrm{Sc}(\mathrm{OTf})_{3}>\mathrm{Fe}(\mathrm{OTf})_{2}>\mathrm{Ga}(\mathrm{OTf})_{3}$ (Table 28, entries 1, 11-13). Unfortunately, the use of a chiral ligand, Pybox, did not induce asymmetric induction; cycloadduct $\mathbf{4 3 3}$ was obtained as a racemic mixture as determined by HPLC analysis (Table 28, entry 11). The results shown in Table 28 were partly confirmed when the reaction was monitored by ${ }^{1} \mathrm{H}$ NMR (Table 29).

Table 29. Monitoring the reaction by NMR.

| Entry | Time | $\mathbf{2 4 2}$ | $\mathbf{4 3 2}$ | $\mathbf{4 3 3}$ | $\mathbf{4 3 5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | 0.2 | 1 | 0.2 | 0.06 |
| 2 | 3.5 h | 0.13 | 1 | 0.7 | 0.08 |
| 3 | 12 h | - | 1 | 1.4 | - |
| 4 | After NaOAc of compounds |  |  |  |  |
| addition | - | 1 | 3 | - |  |
| 5 | After NaOH <br> addition | - | 1 | 11 | - |

Hence, it was observed from Table 29 that when imine $\mathbf{2 4 3}$ was reacted with methyl vinyl ketone 164 in the presence of a Lewis acid, then after one hour the isoquinolium salt $\mathbf{4 3 2}$ was formed as the major product, with a small proportion of the salt $\mathbf{4 3 2}$ also cyclising to product 433 (Table 29, entry 1). Over time, the amount of cyclised product $\mathbf{4 3 3}$ relative to the isoquinolium salt $\mathbf{4 3 2}$ increases (Table 29, entry 2). By the time all of the imine $\mathbf{2 4 3}$ has been consumed, the amount of cyclised product $\mathbf{4 3 3}$ observed is greater than that of the isoquinolium salt 432 (Table 29, entry 3). It was also confirmed that usage of NaOAc as a mild base cyclised $\mathbf{4 3 2}$ to $\mathbf{4 3 3}$ (Table 29, entry 4), whilst usage of NaOH base afforded higher conversion of $\mathbf{4 3 2}$ to $\mathbf{4 3 3}$ (Table 29 , entry 6 ).

Thus, in terms of mechanism, it was proposed that the formal [4+2]-aza-Diels-Alder reaction using imine 243 and enones 183 (where $R \neq L G$ ) in the presence of a Lewis acid goes through a different mechanism depending upon how strong a Michael acceptor the enone $\mathbf{1 8 3}$ was. Because methyl vinyl ketone $\mathbf{1 6 4}$ is a good Michael acceptor, the mechanism is believed to go through a Michael-Mannich pathway. Evidence for this included the fact that the isoquinolium salt 432 (the Michael product) was isolated, which in turn cyclised most effectively in the presence of a base in order for the subsequent Mannich reaction to occur (Scheme 63).

Scheme 63. Proposed Mechanisms for the formal [4+2]-cycloaddition using different enones (where $\mathrm{R} \neq \mathrm{LG}$ ).

In the case of 4-phenyl-3-buten-2-one 348, it was believed that the mechanism of formation of 431 involves a Mannich-Michael pathway (Scheme 63). This was further attributed to the fact that no isoquinolinium salt was isolated, and no base was needed to help with the cyclisation. Hence, the reaction is likely to involve an activated enone of type $\mathbf{4 3 6}$ in order to perform a Mannich reaction with imine $\mathbf{2 4 3}$ to form the Mannich product 437. This would then cyclise to form a species of type 438, where compound 431 would be formed after tautomerisation.

The scope of this reaction was further investigated using different cyclic and acyclic imines. This was monitored by TLC and ${ }^{1} \mathrm{H}$ NMR analysis over a period of a week. However, no cycloadduct was isolated form the reaction mixtures (Table 30).

164

Table 30. Reaction of methyl vinyl ketone $\mathbf{1 6 4}$ with different imines.

| Entry | Imine | Cycloadduct <br> obtained? |
| :--- | :--- | :--- |
|  | No |  |
| 2 |  | No |

Interestingly, when the imine 324 was reacted with methyl vinyl ketone 164 in the presence of a Lewis acid without any subsequent treatment with base, a new compound 443 was isolated (Equation 38).

Equation 38

Compound 443 was only isolated in very small amounts (5\%) and confirmed by HSQC and HMBC. In order for $\mathbf{4 4 3}$ to have been formed, the imine $\mathbf{3 2 4}$ would have hydrolysed to its amine 186 and aldehyde 322 components, with these reacting with two equivalents of methyl vinyl ketone 164; a proposed mechanism has been laid out in Scheme 64. The other components observed in the reaction mixture were starting materials and allylamine 186.

Scheme 64. Proposed mechanism for the formation of compound 443 , where $\mathrm{R}=\mathrm{ally} \mathrm{l}$ and $\mathrm{LA}=\mathrm{Yb}(\mathrm{OTf})_{3}$.

It was also deemed interesting to directly compare the methyl vinyl ketone $\mathbf{1 6 4}$ results for the $[2+2+2]$-reaction. Hence, it was decided to see if different bis-methyl-ketonesubstituted products could be formed with varying degrees of saturation by employing the addition of imines to different enones. This was investigated by reacting imine 243 with enones 164 and $\mathbf{3 5 0}$ in order to determine if this formed the bis-methylketone 453 (Equation 39).

Equation 39

The reasoning behind Equation 39 was that enone $\mathbf{1 6 4}$ (lacking an electron-donating methoxy group) would act as a better Michael acceptor towards imine $\mathbf{2 4 3}$ compared to enone $\mathbf{3 5 0}$, hence, forming the isoquinolinium salt 432. Subsequently, enone $\mathbf{3 5 0}$ would act as a better electrophile than $\mathbf{1 6 4}$ towards attacking the isoquinolinium salt 432 via a Mannich reaction. Subsequent cyclisation and elimination of methanol could afford 453.

In order to be certain that imine $\mathbf{2 4 3}$ attacked enone $\mathbf{1 6 4}$ first, enone $\mathbf{3 5 0}$ was added to the reaction mixture one hour after the first enone $\mathbf{1 6 4}$ (Equation 40). After purification by silica gel chromatography, it was observed that only methyl vinyl ketone $\mathbf{1 6 4}$ had reacted with imine $\mathbf{2 4 3}$ to form the iminium salt $\mathbf{4 3 2}$ as the major product, along with some cyclised product 433. From the crude ${ }^{1} \mathrm{H}$ NMR, it was observed that the enone $\mathbf{3 5 0}$ was unreacted, showing that diacetyl-piperidines of type 453 cannot be formed by this method.

Equation 40

In summary, it has been observed that when reacting cyclic imines with enones that do not have a leaving group in the $\beta$-position, in the presence of a Lewis acid, a formal [4+2]-aza-Diels-Alder cyclisation takes place in order to form piperidine derivatives. The cyclisation goes through a stepwise Mannich-Michael or MichaelMannich pathway, depending on how strong a Michael acceptor the enone is. When the reaction goes through the Michael-Mannich pathway (e.g. when using methyl vinyl ketone), a base is needed to promote the cyclisation after the initial Michael addition reaction. No extra additives are necessary in the Mannich-michael pathway.

### 3.8 Synthesis of new bifunctional aminoboronic acid catalysts

Through exploring traditional Lewis acid-catalysed aza-Diels-Alder reactions, two novel cycloaddition reactions were serendipitously discovered: formal $[2+2+2]$ - and [1+2+1+2]-cyclisation pathways. For the formal [4+2]-cycloaddition using enones without a leaving group on the $\beta$-position, the aza-Diels-Alder reaction was deemed to proceed through a stepwise Mannich-Michael mechanism (depending on the enone used). In order to advance this aza-Diels-Alder methodology, it was decided to investigate the use of aminoboronic acids as catalysts; ${ }^{191}$ variances of these catalysts have been shown successfully catalyse a range of reactions, from asymmetric direct amide formation ${ }^{192}$ to asymmetric aldol reactions. ${ }^{193}$ In particular, the aminoboronic acids of type $\mathbf{4 5 4}$ used in the asymmetric enamine-based aldol reaction have been shown to catalyse the aldol reaction in high yield and enantiomeric excess (ee), with greater ee being obtained when making the boron more Lewis acidic through in situ esterification of the boronic acid. ${ }^{194}$ We were interested in examining the reactivity scope of these aminoboronic acids that work through enamine activation.

Similar to L-proline, these bifunctional aminoboronic acid catalysts 454 consist of a basic amine group and a Lewis acidic boron group (carboxylic acid group for L-proline), with the advantage of circumventing the solubility problems associated with L-proline. Hence, the first aim was to synthesise these aminoboronic acids in order to investigate their activity as chiral catalysts, especially in the MannichMichael (or vice versa) formal cycloaddition reaction.

Previously, the aminoboronic acids of type $\mathbf{4 5 4}$ with side chains of $\mathrm{n}=0-2$ had been synthesised and investigated in the aldol reaction. ${ }^{161}$ Hence, it was decided to synthesise the $\mathrm{n}=3$ catalyst in order to compare it with the shorter chain analogues and study their potential for accessing piperidine derivatives.

### 3.8.1 Racemic catalyst synthesis

In order to determine how the chain length between the nitrogen and boron atoms affected catalyst properties in the aza-Diels-Alder reaction, aminoboronic catalyst 457, with the nitrogen and boron atoms separated by four carbon atoms, was synthesised, initially using the procedure outlined in Scheme 65.

Scheme 65. Proposed synthetic route to catalyst 457.

Protection of pyrrolidine 356 was straightforwardly performed with di-tert-butyldicarbonate in ethanol, affording $N$-boc-pyrrolidine 455 in good $86 \%$ yield (Scheme 66 ).

Scheme 66. Synthesis of catalyst pre-cursor $\mathbf{4 5 6}$ from pyrrolidine.

The deprotonation of $N$-Boc pyrrolidine 455 was then performed using sec-BuLi followed by allylation with allylbromide to give product 456 in $80 \%$ yield (Scheme 66). This reaction could be performed on gram quantities.

It was interesting to observe from the ${ }^{13} \mathrm{C}$ NMR spectrum of $\mathbf{4 5 6}$, that the product was a mixture of two carbamate rotamers. When ${ }^{13} \mathrm{C}$ NMR analysis was performed at room temperature, two carbon peaks were observed for the carbons denoted with an asterisk in Figure 14. When the ${ }^{13} \mathrm{C}$ NMR was performed at a higher temperature $\left(50{ }^{\circ} \mathrm{C}\right)$, the two peaks for each of the individual carbon atoms merged into one, confirming the rotameric effects.

vs.

Figure 14. The two rotamers of 456, where the asterisks signify the carbons exhibiting two peaks by ${ }^{13} \mathrm{C}$ NMR at rt .

In order to access the potential aminoboronic catalyst 456, a catecholborane hydroboration of $\mathbf{4 5 6}$ was attempted under standard reaction conditions. ${ }^{195}$ Heating catecholborane $\mathbf{4 5 8}$ with allyl derivative $\mathbf{4 5 6}$ at $100^{\circ} \mathrm{C}$ for 1 h gave, after workup, a major crude product. ${ }^{1} \mathrm{H}$ NMR suggested that this major component was the deprotected starting material, i.e. 466, on the basis of the allylic peaks (5.4 and 4.9 $\mathrm{ppm})$ being present, along with a lack of a Boc peak at 1.4 ppm . This suggested that catecholborane $\mathbf{4 5 8}$ was too Lewis acidic to hydroborate 456; instead interacting with the carbonyl oxygen of the Boc group and triggering cleavage. A plausible mechanism explaining this is shown in Scheme 67.

Scheme 67. Boc deprotection using catecholborane, where $\mathrm{R}=$ allyl.

Because catecholborane appeared to be too Lewis acidic for the hydroboration reaction of 456, the borane $\left(\mathrm{BH}_{3} \cdot \mathrm{THF}\right)$ was employed instead (Scheme 68). ${ }^{195}$ This reaction was performed in THF at $0^{\circ} \mathrm{C}$, and was subsequently quenched with MeOH . A prominent new spot by TLC analysis showed that a major new compound was
formed. ${ }^{1} \mathrm{H}$ NMR suggested this was compound 467 on the basis of: 1) no allylic peaks being observed at 5.4 and $4.9 \mathrm{ppm} ; 2$ ) the Boc group being present at 1.4 ppm ; and 3) upfield $\mathrm{BCH}_{2}$ and $\mathrm{BCH}_{2} \mathrm{CH}_{2}$ peaks at 0.8 and 1.3 ppm respectively. However, the peaks were not completely clean, and it was obvious that some minor material was present. The ${ }^{11} \mathrm{~B}$ NMR peak was in the expected region ( 32 ppm ) for a boronate derivative.

Scheme 68. Hydroboration of compound 456 using borane.

The crude 467 was protected with pinacol to form 468, in order to make the compound more stable and easier to handle and characterise (Scheme 68). After purification by silica gel chromatography, compound 468 was isolated ( $26 \%$ ) along with a second compound, which was proposed to have structure 469. This was on the basis of the Boc and pinacol peaks being observed at 1.4 and 1.2 ppm respectively by ${ }^{1} \mathrm{H}$ NMR, along with no upfield $\mathrm{BCH}_{2}$ peaks observed. Instead, a lower field 3.6 ppm signal was observed, which would account for the $\mathrm{BOCH}_{2}$ protons. The ${ }^{1} \mathrm{H}$ NMR of 469 also gave a higher integration than expected in the $1.4-1.9 \mathrm{ppm}$ region, possibly due to H -bonding with water. Hence, the integration was approximately in line with what was expected, especially when a $\mathrm{D}_{2} \mathrm{O}$ exchange was performed.

Synthesis of 468 was also performed from 456 in a one-pot reaction without evaporating the MeOH prior to the pinacol protection (Equation 41). This strategy also gave a similarly low yield of 468 (20\%).

## Equation 41

Hence, it was decided to try the hydroboration reaction using IPC-borane 470. Commercial IPC-borane as the TMEDA complex 469 was used, however, no reaction occurred if the TMEDA was not removed beforehand. Hence, the IPC-borane 469 was treated with $\mathrm{BF}_{3}$ etherate in order to complex the TMEDA and release the free IPC-borane 470. The resulting TMEDA•2BF 3 complex was unreactive and could be left in the reaction mixture. ${ }^{196}$ Thus, it was thought that subsequent hydroboration of 456 with 470 would give 471, following literature procedures. ${ }^{197}$ After treating 471 with acetaldehyde this would give the boronate ester 472, whereby the boronic acid 473 could be retrieved after work up (Scheme 69).

Scheme 69. Hydroboration of compound 456 using IPC-borane.

In practice, the steps to form the boronic acid $\mathbf{4 7 3}$ were not straightforward. Isolation of boronic acid 473 was attempted by separating 473 in the aqueous layer from the organic layer as a salt. However, the combined aqueous extracts also contained other salts, including TMEDA $\cdot 2 \mathrm{BF}_{3}$. Hence, compound $\mathbf{4 7 3}$ could not be isolated through this method. Not knowing how stable the boronate ester 472 was, it was refrained from purifying at this stage in case 472 would decompose.

At the same time, hydroboration of $\mathbf{4 5 6}$ with pinacol borane $\mathbf{4 7 4}$ was attempted using metal catalysis. Literature conditions were followed using Wilkinson's catalyst $\left(\mathrm{RhCl}\left(\mathrm{PPh}_{3}\right)_{3}\right)^{198}$ and an iridium complex $\left([\mathrm{Ir}(\operatorname{cod}) \mathrm{Cl}]_{2}\right)^{199}$ respectively (Scheme 70).

Scheme 70. Hydroboration of $\mathbf{4 5 6}$ using metal catalysis.

Through these methods, it was found that the pinacol protected boronate ester 468 was stable to isolation after purification by silica gel chromatography by either catalytic process. The iridium catalyst was the superior catalyst, being higher yielding and faster reacting. Subsequent heating of 468 for 2.5 hours in $20 \%$ (aq) HCl gave both boronate and Boc deprotection, and afforded aminoboronic acid salt 473 in quantitative yields.

Through a combination of ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}, \mathrm{COSY}$, HSQC and TOCSY NMR, it was confirmed that the product was indeed compound 473, with the ${ }^{11}$ B NMR showing a broad peak at $35-36 \mathrm{ppm}$. The ${ }^{1} \mathrm{H}$ NMR peak of the $\mathrm{CH}_{2}$ group next to the boron was very shielded, showing a triplet at 0.6 ppm .

Compound 473 was also obtained when directly heating the crude 468 in acid followed by evaporation and azeotropic removal of volatile components, and thereby preventing the need to purify 468 . Through this method (Scheme 71), 468 was obtained in equally high yields, although with slightly lower purity than the method shown in Scheme 70. Boronic acid 473 was found to be harder to handle than
boronate ester 468. Hence, it was preferred to store 468 and convert the necessary amounts to 473 as required.

Scheme 71. Isolation of aminoboronic acid $\mathbf{4 7 3}$ without purification of the precursor 468.

### 3.8.2 Asymmetric Synthesis of the Aminoboronic Acid Catalyst

Having synthesised the racemic aminoboronic acid 473, it was decided to use this as a standard for its asymmetric synthesis in order to test if this compound could induce asymmetry into the aza-Diels-Alder reaction. Hence, an asymmetric synthesis of $\mathbf{4 7 5}$ using a sparteine-mediated lithiation was attempted from $N$-boc-pyrrolidine 455. The results are shown in Table 31.

Table 31. (-)-Sparteine mediated lithiations of $\mathbf{4 5 5}$, carried out under argon at $-78{ }^{\circ} \mathrm{C}$.

| Entry | Condition A | Condition B | Condition C | Condition D | Yield <br> (\%) | $\begin{gathered} \text { ee } \\ (\%) \\ \hline \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | Dry ether, secBuLi, (-)sparteine, 1 h | Allyl bromide | - | - | 64 | 19 |
| 2 | Dry ether, sec- <br> BuLi, (-)- <br> sparteine, 1 h | $\mathrm{CuCN} \cdot 2 \mathrm{LiCl}$ in dry THF, 1 h | Allyl bromide | - | 63 | 69 |
| 3 | Dry ether, (-)sparteine, secBuLi (455 added 30 min after) 6 h | $\mathrm{ZnCl}_{2}$, dry THF, 30 min | $\mathrm{CuCN} \cdot 2 \mathrm{LiCl}$ in dry THF, 30 min | Allyl bromide | 96 | 82 |
| 4 | Dry ether, (-)sparteine, secBuLi ( $\mathbf{4 5 5}$ added 30 min after) 1 h | $\mathrm{ZnCl}_{2}$, dry THF, 30 min | $\begin{gathered} \mathrm{CuCN} \cdot 2 \mathrm{LiCl} \\ \text { in dry THF, } 30 \\ \min \end{gathered}$ | Allyl bromide | 80 | 82 |

When performing the lithiation reactions with $N$-Boc pyrrolidine $\mathbf{4 5 5}$ in the presence of (-)-sparteine, compound 475 was obtained with a low ee (19\%) (Table 31, entry 1). In an attempt to improve on this, the literature reported by Dieter et al. was followed, involving a solution of $\mathrm{CuCN} \cdot 2 \mathrm{LiCl}$ in THF which was added to the reaction mixture after the lithiation step, prior to addition of the electrophile. ${ }^{200}$ However, this method only raised the ee of $\mathbf{4 7 5}$ to $69 \%$ (Table 31, entry 2 ). In order to try and develop on this further, the literature procedure reported by Coldham et al. was followed whereby a solution of $\mathrm{ZnCl}_{2}$ in THF was added to the reaction mixture prior to the $\mathrm{CuCN} \cdot 2 \mathrm{LiCl}$ solution. ${ }^{201} \mathrm{~A}$ further difference with this method involved the lithiation step: the $N$-boc pyrrolidine was added dropwise to a solution of $(-)$-sparteine in sec-BuLi, as opposed to the sec-BuLi being added dropwise to a stirred solution of $N$-boc pyrrolidine and (-)-sparteine. By following this procedure, compound 475 was obtained with $82 \%$ ee (Table 31, entries 3 and 4). It was also observed that the time spent stirring the reaction mixture prior to the addition of $\mathrm{ZnCl}_{2}$ affected the overall yield. Hence, a $96 \%$ yield was obtained when the reaction mixture was stirred for six hours prior to the addition of the $\mathrm{ZnCl}_{2}$, compared to a yield of only $80 \%$ when the reaction mixture was stirred for 1 hour (Table 31, entries 3 and 4 respectively).

### 3.8.2 Structural Studies on the Bifunctional System 478

After synthesising 475, the aminoboronic acid salt 477 was formed following the procedure shown in Scheme 72, with 477 giving a ${ }^{11} \mathrm{~B}$ NMR signal at 35 ppm . Neutralisation of 477 with equimolar amounts of triethylamine was carried out in order to determine the structural effects of the boron-nitrogen functions in 478, i.e. the extent of the nitrogen-boron chelation 479 (Scheme 72).

Scheme 72. Synthesis of the neutral aminoboronic acid 478.

Thus, after stirring $477(\mathrm{n}=3)$ in the presence of triethylamine for five minutes, the ${ }^{11} \mathrm{~B}$ NMR showed two signals: one at 35 ppm and another at 5 ppm ; the 35 ppm signal being free boronic acid 477, presumably still as the HCl salt. When repeating the ${ }^{11} \mathrm{~B}$ NMR after 24 hours, the signal at 35 ppm disappeared, leaving only the signal at 5 ppm due to the neutral aminoboronic acid. The single upfield signal was indicative of complete nitrogen-boron chelation, resulting in six-membered ring formation (479). It was thought the same chelation might occur when the tether distance between the nitrogen and the boron was shortened by one carbon atom $(\mathrm{n}=2)$ as then a stable five-membered chelate ring would be formed, i.e. 481. Thus, it was thought that the more active aminoboronic acid catalyst would be the one where the tether distance between the boron and the nitrogen was reduced by a further carbon atom $(\mathrm{n}=1)$ since in this case, the chelation between the boron and the nitrogen would be unfavourable due to a strained four-membered ring needing to be formed (483) (Figure 15).

Figure 15. Aminoboronic acid chelation.

### 3.8.3 Homoboroproline Synthesis $(n=1)$

The homoboroproline ( $\mathrm{n}=1$ system) was synthesised according to procedures developed by Whiting et al. ${ }^{202}$ in order to compare this catalyst with the $\mathrm{n}=3$ system 477 and see how the chain length affects the reactivity of the reaction. The $S$-enantiomer 488 was synthesised from $N$-Boc pyrrolidine 455 and electrophile 486 through a sparteine-mediated lithiation reaction. Subsequent deprotection of 487 afforded the desired aminoboronic acid salt 488 (Scheme 73).

Scheme 73. Synthesis of the $S$-enantiomer 488.

The $R$-enantiomer 493 was synthesised from L-proline $152,{ }^{202}$ whereby after $N$ Boc protection to 489 , the carboxylic acid was reduced to the alcohol 490 , this
being iodinated to $\mathbf{4 9 1}$ in order to borylate the compound to 492 . Hence, the free aminoboronic acid 493 was obtained in its HCl salt after deprotection of 492 (Scheme 74).

Scheme 74. Synthesis of the $R$-enantiomer 493.

In summary, the aminoboronic acid catalyst $477(\mathrm{n}=3)$ and the homoboroproline 488 and $493(\mathrm{n}=1)$ were synthesised in order to determine how the chain length of the aminoboronic acid affects the reactivity of the aza-Diels-Alder reaction. For a complete comparison, the $\mathrm{n}=2$ system $\mathbf{1 0}$ was obtained from Irene Georgiou. The $\mathrm{n}=3$ system was asymmetrically synthesised in an asymmetric manner using a (-)-sparteine-mediated lithiation procedure, followed by hydroboration using iridium catalysis; the $\mathrm{n}=1$ system was synthesised following literature procedures. ${ }^{202}$

### 3.9 Examination of the Catalytic Potential of Bifunctional Catalysts

Having synthesised the $\mathrm{n}=3$ and $\mathrm{n}=1$ aminoboronic acid systems (see previous section), the next aim was to test their catalytic activities in different reactions, and in particular, the aza-Diels-Alder reaction in order to use the best catalyst for the synthesis of biologically important piperidine systems.

### 3.9.1 Catalysis of the aza-Diels-Alder reaction

The synthesis of $\mathbf{3 5 6}$ was attempted using the aminoboronic acid salt $\mathbf{4 8 8}$ in order to compare and test the aminoboronic acid in a formal aza-Diels-Alder reaction (Equation 42). However, after a week of stirring at room temperature, only starting materials 348 and $\mathbf{3 2 4}$ were observed in the reaction mixture, suggesting that a more Lewis acidic catalyst may be needed.

## Equation 42

Formation of the dihydropyridone 244 was also attempted using organocatalysis. In particular, catalysts 473 and 494 were compared, and the crude reaction mixtures analysed by TLC and LCMS. However, neither reaction showed any dihydropyridone $\mathbf{2 4 4}$ formation. Instead, small amounts of the [2+2+2]-derived dihydropyridine 369 adduct were detected by TLC and LCMS analysis (Table 32).

Table 32. Reaction attempts between imine $\mathbf{2 4 3}$ and methoxy enone $\mathbf{3 5 0}$ using different organocatalysts.

| Entry | Organocatalyst | LCMS analysis of crude | TLC analysis of crude |
| :--- | :---: | :---: | :---: |
|  |  | Imine $\mathbf{2 4 3}$ and <br> dihydropyridine $\mathbf{3 6 9}$ were <br> clearly present | $\mathbf{3 6 9}$ was clearly present |

It was also found that the aminoboronic acid 473 was not sufficiently active to catalyse the Michael-Mannich formal [4+2]-cycloaddition between imine 243 and methyl vinyl ketone 164 (Equation 43). This was probably due to no imminium ion formation to encourage Michael addition, or enamine formation to assist in the Mannich process.

Equation 43

Examination of the literature ${ }^{116}$ revealed that organocatalytic aza-Diels-Alder reactions generally tend to work best when using electron-deficient imines; examples include $N$-sulfonamido imines such as 495 . Hence, it was decided to attempt the aza-Diels-Alder reaction between imine 495, using the aminoboronic acid 473. To begin with, a standard was prepared using Danishefsky's diene 4 (Table 33). However,
when this reaction was attempted using Lewis acid catalysis, the dihydropyridone 496 was not observed (Table 33, entry 1). Instead, when this reaction was heated without a Lewis acid, the dihydropyridone 496 was successfully formed and isolated after purification by silica gel chromatography (Table 33, entry 2 ). Interestingly, product 496 was not observed by LCMS analysis when the reaction was heated in the presence of a Lewis acid (Table 33, entry 3).

Table 33. aza-Diels-Alder reaction for the formation of dihydropyridone 469.

| Entry | Conditions | Yield (\%) |
| :---: | :---: | :---: |
| 1 | $\mathrm{Yb}(\mathrm{Otf})_{3}(20 \mathrm{~mol} \%), \mathrm{rt}, \mathrm{CHCl}_{3}$ | 0 |
| 2 | $100{ }^{\circ} \mathrm{C}$, toluene | 62 |
| 3 | $\mathrm{Sc}(\mathrm{Otf})_{3}(10 \mathrm{~mol} \%), 100^{\circ} \mathrm{C}$, toluene | 0 |

Having obtained the racemic standard 496, an organocatalytic aza-Diels-Alder reaction was subsequently tested between imine 495 and the enone 350 (the enone equivalent of diene 4). The organocatalysts tested were the aminoboronic acid 473 and the imidazoline-based catalyst 494. ${ }^{203}$ The reactions were monitored by LCMS and TLC. The neutral organocatalysts were formed in situ by neutralising their HCl salts with an equimolar amount of triethylamine. However, the dihydropyridone 496 was not observed on any of these attempts (Table 34).

Table 34. Organocatalytic attempts for the synthesis of dihydropyridone 496.

| Entry | Organocatalyst $\left(20 \mathrm{~mol}^{2}\right)$ | Conditions | Yield (\%) |
| :--- | :---: | :--- | :---: |
|  | Toluene, rt | 0 |  |

Since the desired product was not observed in the above reactions (Table 34) when using 4-methoxy-3-buten-2-one $\mathbf{3 5 0}$ as the enone, the reaction was investigated using different enones to determine if this had an impact on the reaction. Hence, the substrates shown in Table 35 were examined, and again monitored by LCMS. However, in all cases, LCMS showed only starting materials and even when the reactions were at reflux, LCMS analysis did not show any product formation. TLC analysis showed complex mixtures, with no clear single products being formed.

Table 35. aza-Diels-Alder attempts between enones and $N$-sulfonamido imine $\mathbf{1 0}$.
Entry Enone
*Equimolar amounts of $\mathrm{NEt}_{3}$ were added to neutralise the catalyst.

These reactions suggest that the aminoboronic acid $\mathbf{4 7 3}$ may not be sufficiently Lewis acidic (in its present form) to catalyse the aza-Diels-Alder reaction or more likely that boron-nitrogen chelation prevents reactivity. Hence, it was decided to probe the reactivity of these different aminoboronic acids in reactions that have already been shown to be catalysed by aminoboronic acids, such as the aldol reaction. ${ }^{161}$

### 3.9.2 Catalytic Studies on the Aldol Reaction

Discovered in $1838,{ }^{204}$ the aldol reaction ${ }^{205}$ is perhaps one of the oldest named reactions in organic synthesis, and has been extensively researched. The reaction combines two carbonyl compounds (originally aldehydes) to form a new $\beta$-hydroxy
carbonyl compound. The term aldol was derived from the aldehyde and alcohol functional groups that were observed in many of the products.

Considering that the aldol reaction has been extensively studied, it was deemed sensible to test the reactivity of to aminoboronic acid $\mathbf{4 7 3}$ within this reaction, and at the same time compare it against other proline-based catalysts, ${ }^{206}$ i.e. L-proline 152 and the imidazoline based catalyst 494 (Figure 16). ${ }^{207}$ Aminoboronic acids 493 and 508 with varying chain lengths were also used to compare their reactivity with that of 473. (Table 36).

Table 36. Organocatalytic aldol reactions, using 1 mmol of reagents.

Figure 17. Isolated compounds from Table 36.

The aldol reaction between para-nitrobenzaldehyde 354 and acetone $314(\mathrm{R}=\mathrm{Me})$ was initially carried out (Table 36, entries 1-8) and it was found that having some Lewis acidic character in the organocatalyst was important. Without it (i.e. catalyst 494) the reaction did not proceed (Table 36, entry 7). As expected, ${ }^{206}$ L-proline 152 gave good yields of the aldol product, with similar results obtained when using acetone or DMSO as the solvent (Table 36, entries 6 and 8).

It had previously been found by Irene Georgiou (PhD student, Whiting group) that the optimum conditions to perform the aldol reaction using aminoboronic acids as the catalyst was with the $\mathrm{n}=1$ system 493 in DMF at 0.2 M , where high yields and enantiomeric excess of the aldol product $\mathbf{5 0 5}$ were obtained over six hours ( $88 \%, 95 \%$ ee). ${ }^{194}$ Nonetheless, under these diluted reaction conditions, the $\mathrm{n}=3$ system 473 showed no reactivity after 24 hours. However, having a concentrated reaction ( 2 M vs. 0.2 M ) gave interesting results when using the aminoboronic acids (Table 36).

With catalyst $473(\mathrm{n}=3)$, the reaction went to completion after 72 hours and interestingly, the major product obtained was the racemic double aldol product 506 (Table 36, entry 1). The formation of the double aldol product was confirmed by obtaining its X-ray crystal structure (Figure 18).

Figure 18. X-ray molecular structure of compound 506.

When using the catalyst $493(\mathrm{n}=1)$ or $508(\mathrm{n}=2)$, however, the aldol reaction was completed within a few hours, with the major product obtained as the single aldol product 505 (Table 36, entries 2 and 4 respectively). The catalysts $\mathbf{4 9 3}$ and $\mathbf{5 0 8}$ were also reacted for 72 hours to see if the double aldol product could be formed to a greater extent if the reaction was left for longer. However, on both occasions the major product was still the aldol product $\mathbf{5 0 5}$, followed by the condensation product 355 (Table 36, entries 3 and 5). No double aldol product 506 was observed with catalyst $508(\mathrm{n}=2)($ Table 36, entry 5). Interestingly, small amounts of the double aldol product 506 were observed with catalyst $493(\mathrm{n}=1)$ when the reaction was left to react for 72 hours (Table 36, entry 3). Additionally, when catalyst $473(\mathrm{n}=3)$ was used, small amounts of the tetrahydropyran $\mathbf{5 0 7}$ were isolated as a single diastereoisomer, which presumably arose from the elimination of the double aldol product $\mathbf{4 8}$ followed by cyclisation (Scheme 75).

Scheme 75. Formation of the tetrahydropyran $\mathbf{5 0 7}$ from the double aldol product 506.

In order to see if the aminoboronic acid $473(\mathrm{n}=3)$ would preferentially form the aldol product 510 when the ketone could only enolise in one direction, the aldol reaction was performed between $p$-nitrobenzaldehyde 354 and $p$-chloroacetophenone $509(\mathrm{R}=p-\mathrm{ClPh})$ following procedures laid out by Wang et al. ${ }^{208}$ (Table 36, entries 911) (Equation 44). The aminoboronic acid $473(\mathrm{n}=3)$ was shown to be the more active catalyst compared with L-proline $\mathbf{1 5 2}$ since some of the aldol product $\mathbf{5 1 0}$ was isolated ( $<5 \%$ ). Interestingly, ${ }^{1} \mathrm{H}$ NMR and MS analysis suggested that some of the double aldol product 511 was formed in a slightly higher amount (5\%). However, not enough product 511 was isolated to allow confirmation of the structure by ${ }^{13} \mathrm{C}$ NMR (Table 36, entry 9).

Equation 44

When using L-proline 152, the aldol reaction (Equation 44) was slow, with minimal amounts of the aldol product 510 being obtained (Table 36, entry 10). Unsurprisingly, when using acetone as the solvent instead of DMSO, only the aldol product $\mathbf{5 0 5}$ between $p$-nitrobenzaldehyde 354 and the more reactive ketone (acetone) was observed; p-chloroacetophenone $509(\mathrm{R}=p$-ClPh) remained unreacted (Table 36, entry 11). This aldol reaction was significantly less reactive than when using acetone as the ketone, probably due to the aromatic ring stabilising the initial iminium ion that would be formed between the ketone and the catalyst ( 513 and 514), thus preventing the enamine formation $\mathbf{5 1 5}$ with the methyl group (Scheme 76).

Scheme 76. Resonance stabilisation of the imminium species 514.

Overall, these results (Table 36) suggest that the aminoboronic catalyst $473(n=3)$ is oddly only active when used under highly concentrated reaction conditions ( 2 M ), whilst still being slower than catalysts $493(\mathrm{n}=1)$ and $508(\mathrm{n}=2)$. When applied to the aldol reaction, this catalyst $\mathbf{4 7 3}(\mathrm{n}=3)$ is the only one to favour formation of the double aldol products 506 and 511 over the single aldol products 505 and 510 respectively. Higher conversions were obtained when using the more reactive ketone acetone 314 over $p$-chloroacetophenone 509. In addition, the fact that no reactivity was observed when using the imidazoline catalyst 14 confirms the probable need to have a Lewis acidic section on the organocatalyst for the aldol reaction to proceed smoothly.

### 3.9.3 Examination of the Mannich Reaction

Considering a main aim of this work was to develop an aminoboronic acid to act as an organocatalyst in the aza-Diels-Alder reaction, and that the formal aza-Diels-Alder reaction is generally accepted to go through a Mannich-Michael pathway, the Mannich reaction was explored using the aminoboronic acids. If these catalysts could not catalyse a Mannich reaction, it meant that they would not be able to catalyse the aza-Diels-Alder reaction either. Such a study would aid in determining which of the reaction steps, i.e. the Mannich or Michael reaction, was the most problematic step for aminoboronic acids to catalyse. Fully understanding the Mannich versus Michael reactions would also assist in understanding what necessary properties the
organocatalyst needed to enable the Mannich-Michael reaction to occur and hence, this could be applied to the efficient formation of piperidine systems.

A Mannich reaction was reported by Bella et al. in which cyclic imine $\mathbf{3 3 3}$ was reacted with acetone $\mathbf{3 1 4}$ in the presence of L-proline 152 to form the Mannich product $\mathbf{5 1 6}$ in reasonable yield and ee (Equation 45). ${ }^{167}$

## Equation 45

In order to test the scope of this procedure, the Mannich reaction between cyclic imine $\mathbf{2 4 3}$ and acetone $\mathbf{3 1 4}$ in the presence of l-proline 152 was performed in an attempt to form the Mannich product 517 (Equation 46). However, the Mannich product 517 was not formed under these conditions.

## Equation 46

Hence, it was decided to investigate a more developed Mannich reaction between hydroxyacetone 518, $p$-anisidine 120 and $p$-nitrobenzaldehyde 354, in the presence of L-proline 152, following a procedure reported by List et al. ${ }^{209}$ The Mannich product $\mathbf{5 1 9}$ was obtained in $83 \%$ yield (Equation 47) and according to List et al., $\mathbf{5 1 9}$ was obtained with $20: 1 \mathrm{dr}$ and $99 \%$ ee. ${ }^{209}$ However, under these dilute reaction conditions ( 0.2 M ), no reaction occurred when the aminoboronic acid $473(\mathrm{n}=3)$ was used as catalyst.

Equation 47

Nonetheless, aminoboronic acid $473(\mathrm{n}=3)$ was tested to see if it worked on a Mannich reaction between $p$-nitrobenzaldehyde 354, acetone 314 and $p$-anisidine 120 (Equation 48). Monitoring this reaction by TLC revealed that after 24 hours, all of the $p$-nitrobenzaldehyde $\mathbf{3 5 4}$ had been consumed, with the $p$-anisidine $\mathbf{1 2 0}$ being unreacted. After 72 h , TLC analysis showed that most of the $p$-anisidine $\mathbf{1 2 0}$ was still unreacted. Despite this, the reaction mixture was purified by silica gel chromatography and it was revealed that the major component was the imine 326 (29\%). The aldol reaction between $p$-nitrobenzaldehyde 354 and acetone 314 had also taken place, although small amounts of these products ( $\mathbf{3 5 5}, 505$ and 506) were obtained. The Mannich adduct $\mathbf{5 2 0}$ was a minor product, being isolated in low yield (6\%).

## Equation 48

Turning our attention to more electron-deficient imines, the Mannich reaction between imine 495 and acetophenone 89 was also attempted. However, no product 521 was detected by LCMS, neither after reacting at room temperature or heating up to $70{ }^{\circ} \mathrm{C}$ (Equation 49). Instead, the starting materials were observed amongst other
peaks by LCMS analysis, while TLC analysis showed a mixture of starting materials and products.

Equation 49

### 3.9.4 Examination of Michael Reaction Catalysis

The ring-closing process of the aza-Diels-Alder reaction to form piperidine products is generally accepted to go via a Michael reaction; a reaction that also needs to be optimised to successfully apply new organocatalysts. Chaudhuri et al. have specified that the aza-Michael reaction can be effectively performed in water using boric acid as a catalyst. ${ }^{210}$ Taking this as a starting point, this reaction was investigated.

The aza-Michael reaction was successfully performed in water using methyl vinyl ketone 164 and dibenzylamine 522. In order to see if the boronic acids could also be active catalysts, the same reaction was subsequently attempted using phenylboronic acid as the catalyst, with product 523 isolated in $55 \%$ yield (Equation 50) after 12 hours.

## Equation 50

When using methyl vinyl ketone 164, the aminoboronic acid 477 was shown to be effective for this aza-Michael reaction as outlined in Equation 51.

## Equation 51

In order to compare the boronic acids 477, 488, phenylboronic and boric acid in the Michael reaction between methyl vinyl ketone 164 and dibenzylamine 522, the reaction was performed in $\mathrm{CDCl}_{3}$ and monitored over time by ${ }^{1} \mathrm{H}$ NMR analysis. The use of triethylamine on its own was also monitored in order to monitor the catalystfree background reaction (Table 37). From these studies, it was observed that when using this solvent $\left(\mathrm{CDCl}_{3}\right)$, complete conversion to the Michael product $\mathbf{5 2 3}$ occurred within half an hour for all the catalysts (Table 37, entries 1-4). Conversely, when monitoring the background reaction using triethylamine as the additive, it took five hours for complete conversion to product $\mathbf{5 2 3}$ to occur thus confirming that the boronic acids are indeed catalysing the reaction.

Table 37. Monitoring of the Michael reaction by ${ }^{1} \mathrm{H}$ NMR analysis.

| Entry | Additive A (10 mol\%) | Additive B (10 mol\%) | Time taken for $100 \%$ conversion to 523 |
| :---: | :---: | :---: | :---: |
| 1 | $\mathrm{B}(\mathrm{OH})_{3}$ | - | $<0.5 \mathrm{~h}$ |
| 2 | $\mathrm{PhB}(\mathrm{OH})_{2}$ | - | $<0.5 \mathrm{~h}$ |
| 3 | B(OH) ${ }_{2}$ | $\mathrm{NEt}_{3}$ | $<0.5 \mathrm{~h}$ |
| 4 | $\mathrm{B}(\mathrm{OH})_{2}$ | $\mathrm{NEt}_{3}$ | $<0.5 \mathrm{~h}$ |
|  | 477 |  |  |
| 5 | $\mathrm{NEt}_{3}$ | - | 5 h |

These results suggest that aminoboronic acids can catalyse the Michael reaction as effectively as boric and phenylboronic acid and this paves the way for investigating whether chiral aminoboronic acids can cause asymmetric induction within the Michael reaction when using different substituted enones. Hence, this confirms that more research is needed into the Mannich reaction over the Michael reaction when utilising aminoboronic acids as catalysts. The main reason why the Mannich reaction proved to be problematic when using these catalysts could be because the aminoboronic acids in their current form are simply not sufficiently Lewis acidic to catalyse the reaction.

Chapter 4:
CONCLUSIONS AND FUTURE WORK

## 4. Conclusions and Future Work

It was confirmed that the construction of a robust, efficient and general organocatalytic aza-Diels-Alder process is a real and still ongoing challenge. However, through the screening of different Lewis-acid catalysed aza-Diels-Alder reactions, a few novel cyclisation routes were discovered, dependent on the reagents and reaction conditions used.

When using 4-methoxy-3-buten-2-one, or its (Danishefsky's) diene equivalent, different novel dihydropyridone and dihydropyridine ring systems could be formed when using different imines; each going through a different formal cycloaddition pathway. The acyclic imines were hydrolysed to their amine and aldehyde starting components when reacted with 4-methoxy-3-buten-2-one in the presence of a Lewis acid. It was also found that the stoichiometry and hygroscopic nature of the Lewis acid was important (Scheme 77).

Scheme 77. The different piperidine rings that are obtained when reacting Danishefsky's diene or its enone equivalent with imines.

Further investigation of the formal [4+2]-cycloaddition process provided a greater mechanistic insight into the metal-catalysed aza-Diels-Alder pathway. When using
enones that did not contain a leaving group on the $\beta$-position, a formal [4+2]cycloaddition occurred when the enone was reacted with an imine and a Lewis acid. Dependent on how good a Michael acceptor the enone was dictated whether the mechanism proceeded via a Mannich-Michael or a Michael-Mannich pathway (Scheme 78).

Scheme 78. The different mechanistic pathways within the [4+2]-formal cyclisation when using enones that do not contain a leaving group on the $\beta$-position.

Future work with these metal-catalysed cyclisations includes testing out these reactions using an increased substrate database. In addition, it would be beneficial to find the optimum base for the Michael-Mannich formal [4+2]-cycloaddition between methyl vinyl ketone and imines.

The asymmetric syntheses of the aminoboronic acids were successfully accomplished. However, regarding their reactivity, it was concluded that these aminoboronic acids were not sufficiently Lewis acidic to undergo an aza-Diels-Alder reaction. In particular, the catalyst $473(\mathrm{n}=3)$ was inactive due to strong intramolecular N -B chelation. Despite this, under very concentrated conditions the catalyst $473(\mathrm{n}=3)$ was shown to be active (although slow) in the aldol reaction in order to give predominantly the double aldol product. However, due to the N-B chelation the homoboroproline $493(\mathrm{n}=1)$ was deemed to be the optimum aminoboronic acid in terms of the tether distance between the nitrogen and the boron.

Future work regarding the aminoboronic acids includes the construction of a more Lewis acidic aminoboronic acid catalyst in order to test the Mannich reaction, prior to testing on the aza-Diels-Alder reaction. Examples of more Lewis acidic aminoboronic
acids whose syntheses could be attempted include: 1) having two fluorine atoms on the carbon adjacent to the boron (524); or 2) attaching strong electron-withdrawing groups such as pentafluorophenol (PFP) to the boron atom (525).

After synthesising the more Lewis acidic aminoboronic acids, their activity can be tested within the aldol, Mannich and Michael reactions, with the ultimate aim of determining whether they can catalyse the aza-Diels-Alder reaction. In addition, the Michael addition reaction can be further investigated regarding the synthesis of chiral products. The kinetics can also be looked at in order to prove the relative reactivities of the different catalysts.

The field of the organocatalytic aza-Diels-Alder reactions has advanced slowly in the past few years. This shows the challenge in constructing a truly robust organocatalytic system for this reaction, one that will no doubt be achieved within the near future. Once developed, these catalysts would be able to be used in an atom-economical aza-Diels-Alder reaction in order to synthesise different biologically active piperidine ring-containing compounds.

Chapter 5:
EXPERIMENTAL

## 5. Experimental

### 5.1 General Experimentation

All starting materials, including solvents, were used as received without further purification, unless otherwise stated. All reactions were performed under air unless otherwise specified. Reactions were monitored by TLC analysis carried out on Polygram SIL G/UV ${ }_{254}$ plastic backed silica gel plates, and were visualised under a UV lamp operating at short ( 254 nm ) and long ( 365 nm ) wavelength ranges. Visualisation was aided by staining with $\mathrm{I}_{2}$ or by dipping plates into an alkaline potassium permanganate or anisaldehyde solution. Flash silica gel column chromatography was carried out on Davisil Silica Gel, 60-200 mesh. $3 \AA$ Molecular sieves were activated by heating to $150^{\circ} \mathrm{C}$. Concentration of the reaction mixture in vacuo is the removal of solvent under reduced pressure. ${ }^{1} \mathrm{H}$ NMR spectra were recorded on either Brüker Avance-400, Varian-Mercury 500 or Varian VNMRS 700 MHz spectrometers, operating at ambient probe temperature, unless otherwise stated. Peaks are reported as singlet (s), doublet (d), triplet ( t ), quartet ( q ), broad (br), some combinations of these, or multiplet (m), and coupling constants $(J)$ in hertz $(\mathrm{Hz})$. ${ }^{13} \mathrm{C}$ NMR spectra were recorded on Varian Brüker Avance-400, Varian Mercury-500 or Varian VNMRS 700 instruments at frequencies of 101,126 or 176 MHz respectively, unless otherwise stated. The chemical shifts are reported in ppm relative to residual signals of the solvent, ${ }^{211}$ and couplings are as follows: $\mathrm{s}=0$ protons; $d=$ odd number of protons; $t=$ even number of protons, attached to the carbon atom, as determined by ${ }^{13} \mathrm{C}$ DEPT NMR. ${ }^{11} \mathrm{~B}$ NMR spectra were recorded on a Brüker Avance- 400 instrument at a frequency of 128 MHZ and the chemical shifts are reported in ppm. Deuterated chloroform $\mathrm{CDCl}_{3}$, DMSO and $\mathrm{D}_{2} \mathrm{O}$ were used as deuterated solvents for all NMR experiments. Mass spectra for liquid chromatography mass spectrometry (LCMS) were obtained using a Waters LCT spectrometer, and accurate mass spectrometry obtained on a Finnigan LTQ-FT using the electrospray in positive ion mode (ES+) to generate ions, unless otherwise stated. IR spectra were recorded on a Perkin-Elmer Paragon 1000 FT-IR spectrometer. Chiral HPLC analyses
were performed on a Perkin Elmer system equipped with a Perkin Elmer Series 200 pump, a Perkin Elmer Series 200 autosampler and a Perkin Elmer Series 200 Diode array detector. Elemental analysis was performed using an Exeter Analytical E-440 Elemental Analyser. Optical rotations were taken using a JASCO P-1020 polarimeter and $[\alpha]_{D}$ values are given in $\operatorname{deg} \mathrm{cm}^{2} \mathrm{~g}^{-1}$. Melting points were measured, where appropriate, with a Gallenkamp Variable Heater melting point apparatus and are uncorrected.

### 5.2 General Procedures

## Procedure for the attempted synthesis of 334 (Scheme 56)

To phenylhydrazine ( $2 \mathrm{~mL}, 20 \mathrm{mmol}$ ) in hexane $(6 \mathrm{~mL})$ under nitrogen at $0{ }^{\circ} \mathrm{C}$ was added isobutyraldehyde $(1.9 \mathrm{~mL}, 21 \mathrm{mmol})$ dropwise. The reaction mixture was stirred at rt for 1 h prior to the slow addition of methanesulfonic acid $(9.6 \mathrm{~mL}$, 148 mmol ) at $0{ }^{\circ} \mathrm{C}$. The reaction mixture was subsequently stirred at rt overnight, neutralised $\left(\mathrm{NaHCO}_{3}\right)$ and monitored by LCMS and ${ }^{1} \mathrm{H}$ NMR. Purification by silica gel chromatography was attempted, however, the compound seemed to be unstable in silica.

## Procedure for the one-pot, three-component screening reactions (Table 4)

To a mixture of amine ( 1 mmol ), aldehyde ( 1 mmol ) and enone ( 4 mmol ) in solvent $(2 \mathrm{~mL})$ was added the organocatalyst $(0.2 \mathrm{mmol})$ and the reaction mixtures were stirred at rt . The reaction mixtures were monitored after 24 h and 48 h via TLC analysis ( $1: 1$ to $4: 1$, EtOAc/hexane, as eluent).

Procedure for the one-pot, three-component screening reactions where the imine was formed in situ (Table 5)
A mixture of aldehyde ( 1 mmol ) and amine ( 1 mmol ) in solvent $(2 \mathrm{~mL})$ and $3 \AA$ molecular sieves ( 1 g ) was stirred at rt for 12 h prior to the addition of enone ( 4 mmol and organocatalyst ( 0.2 mmol ). The reaction mixtures were stirred at rt and monitored after 24 h and 48 h via TLC analysis ( $1: 1$ to 4:1, EtOAc/hexane, as eluent).

## Procedure for the imine screening reactions (Table 6)

To a mixture of imine ( 1 mmol ), enone ( 4 mmol ) and $3 \AA$ molecular sieves $(1 \mathrm{~g})$ in solvent ( 3 mL ) was added the organocatalyst $(0.2 \mathrm{mmol})$ and the reaction mixtures were stirred at rt . The reaction mixtures were monitored after 24 h and 48 h via TLC analysis (1:1 to 2:1, EtOAc/hexane, as eluent).

## Procedure for the organocatalysed aza-Diels-Alder reaction (Table 7)

To imine ( 3.5 mmol ) and organocatalyst ( $20 \mathrm{~mol} \%$ ) in solvent ( 40 mL ) was added enone ( 14 mmol ) and the reaction mixture was stirred at rt . If purified, the mixture was concentrated in vacuo and purified by silica gel chromatography (hexane:EtOAc, as eluent).

## Procedure for the Lewis acid catalysed aza-Diels-Alder reaction (Table 8)

To imine ( 1 mmol ) and Lewis acid ( $20 \mathrm{~mol} \%$ ) in solvent ( 2 mL ) was added diene $(1.2 \mathrm{mmol})$ and the reaction mixture was stirred at rt . If purified, the mixture was concentrated in vacuo and purified by silica gel chromatography (hexane:EtOAc, as eluent).

## Procedure for the formation of $\mathbf{Z n C l}_{\mathbf{2}} \cdot \mathbf{E t}_{\mathbf{2}} \mathbf{O}$

$\mathrm{ZnCl}_{2}(0.506 \mathrm{~g}, 5 \mathrm{mmol})$ was dissolved in diethyl ether ( 2.5 mL ) whilst stirring at rt for 15 min to form a 1 M solution of $\mathrm{ZnCl}_{2} \bullet \mathrm{Et}_{2} \mathrm{O}$.

## Procedure for the $\mathbf{Z n C l}_{\mathbf{2}} \cdot \mathbf{E t}_{\mathbf{2}} \mathbf{O}$ catalysed aza-Diels-Alder reaction (Table 8)

To $\mathrm{ZnCl}_{2} \cdot \mathrm{Et}_{2} \mathrm{O}$ ( 2 M in diethyl ether; $2.5 \mathrm{~mL}, 5 \mathrm{mmol}$ ) and diene $349(0.218 \mathrm{~g}$, 1 mmol ) in solvent ( 3 mL ) was added imine $324(0.145 \mathrm{~g}, 1 \mathrm{mmol})$ and the reaction mixtures were allowed to stir at rt for 48 h .

For an acid-base workup: The reaction mixture was washed with $5 \%$ (aq) $\mathrm{HCl}(2 \times$ $5 \mathrm{~mL})$. Saturated (aq) $\mathrm{NaHCO}_{3}(20 \mathrm{~mL})$ was added to the combined aqueous layers and the organics extracted using $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 20 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo.
For an acid workup: The reaction mixture was quenched with $5 \%$ (aq) $\mathrm{HCl}(5 \mathrm{~mL})$, the organic layer separated and the aqueous layer washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \times 5 \mathrm{~mL})$. The combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo.

## Procedure for the catalyst screening for the [4+2]-diene cyclisation (Table 10)

To a Lewis acid ( $20 \mathrm{~mol} \%$ ), 2-ethyl-2-oxazoline ( $0.016 \mathrm{~mL}, 0.16 \mathrm{mmol}$ ) and $3 \AA$ molecular sieves ( 1 g ) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added imine $243(0.05 \mathrm{~g}$, $0.4 \mathrm{mmol})$ and Danishefsky's diene ( $0.08 \mathrm{~mL}, 0.4 \mathrm{mmol}$ ). The reaction mixtures were flushed with nitrogen, stirred at rt and analysed via TLC (EtOAC, as eluent).

Procedure for the phosphine ligand screening for the [4+2]-diene cyclisation (Table 11)

To a phosphine ligand ( $40 \mathrm{~mol} \%$ ), Lewis acid ( $20 \mathrm{~mol} \%$ ), and $3 \AA$ molecular sieves $(1 \mathrm{~g})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added imine $243(0.05 \mathrm{~g}, 0.4 \mathrm{mmol})$ and Danishefsky's diene ( $0.08 \mathrm{~mL}, 0.4 \mathrm{mmol}$ ). The reaction mixtures were flushed with nitrogen, stirred at rt and analysed via TLC (EtOAC, as eluent).

## Procedure for the scaled up [4+2]-diene cyclisation (Table 12)

To a Lewis acid ( $20 \mathrm{~mol} \%$ ), 2-ethyl-2-oxazoline ( $0.016 \mathrm{~mL}, 0.16 \mathrm{mmol}$ ) and $3 \AA$ molecular sieves ( 1 g ) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added imine $243(0.05 \mathrm{~g}$, $0.4 \mathrm{mmol})$ and Danishefsky's diene ( $0.08 \mathrm{~mL}, 0.4 \mathrm{mmol}$ ). The reaction mixtures were flushed with nitrogen and stirred at rt for 48 h . The reaction mixtures were quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(5 \mathrm{~mL})$, diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and brine $(10 \mathrm{~mL})$ and filtered. The mixture was extracted from the filtrate with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$ and the combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$, concentrated in vacuo and purified by silica gel chromatography (4:1, EtOAc:hexane, as eluent).

## Procedure for the $[\mathbf{2 + 2 + 2}]$-screening using trituration to purify (Table 15)

To imine 243 ( $0.131 \mathrm{~g}, 1 \mathrm{mmol}$ ), 4-methoxy-3-buten-2-one ( $0.204 \mathrm{~mL}, 2 \mathrm{mmol}$ ) and additive, in solvent ( 1.5 mL ), was added Lewis acid ( $10 \mathrm{~mol} \%$ ) and the reaction mixture was stirred at rt . After the denoted time, most of the solvent had evaporated, leaving an orange paste. EtOAc was added to the reaction mixture to form a suspension, which was subsequently filtered and the solid washed with EtOAc dropwise.

To imine 243 ( $0.131 \mathrm{~g}, 1 \mathrm{mmol}$ ) and 4-methoxy-3-buten-2-one ( $0.204 \mathrm{~mL}, 2 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1.5 \mathrm{~mL})$ was added Lewis acid ( $10 \mathrm{~mol} \%$ ) and the reaction mixture was stirred at rt. After 48 h , the reaction mixtures were purified by silica gel chromatography.

## Procedure for the $[\mathbf{2 + 2 + 2}]$-cyclisation attempts using different imines (Table 20)

To an imine ( 1 mmol ) and 4-methoxy-3-buten-2-one ( $0.204 \mathrm{~mL}, 2 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(1.5 \mathrm{~mL})$ was added $\mathrm{Sc}(\mathrm{OTf})_{3}(10 \mathrm{~mol} \%)$. The reaction mixture was stirred at rt and monitored via TLC analysis (EtOAc, as eluent).

## 

To an imine ( 1 mmol ) and 4-methoxy-3-buten-2-one ( $0.204 \mathrm{~mL}, 2 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(1 \mathrm{~mL})$ was added $\mathrm{Sc}(\mathrm{OTf})_{3}(10 \mathrm{~mol} \%)$. The reaction mixtures were stirred at rt , monitored via TLC analysis and purified by silica gel chromatography.

Procedure for the $[1+2+1+2]$-cyclisation reaction using aldehydes and amines (Table 22)
To an amine ( 1 mmol ), aldehyde ( 1 mmol ) and 4-methoxy-3-buten-2-one ( 0.204 mL , $2 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1 \mathrm{~mL})$ was added $\mathrm{Sc}(\mathrm{OTf})_{3}(10 \mathrm{~mol} \%)$. The reaction mixtures were stirred at rt, monitored via TLC analysis and purified by silica gel chromatography.

## Procedure for the biological testing

A549 cells were propagated in DMEM medium ( $+10 \%$ fetal calf serum) in 96 well plates and allowed to grow to $50 \%$ confluency at $37{ }^{\circ} \mathrm{C}$ in an atmosphere adjusted to $5 \% \mathrm{CO}_{2}$. The medium was removed by aspiration and replaced with DMEM $+2 \%$ FCS to mimic conditions used during viral infection. 10 fold serial dilutions of each alkaloid from $100 \mu \mathrm{M}$ to 1 nM were made and the cells incubated for 96 hours at $33{ }^{\circ} \mathrm{C}$ (viral growth conditions). As a control, DMSO was added to cells. Cells were visually monitored using light microscopy for any visible changes in morphology, and viability was analysed using an Almar Blue cytoxicity assay. The $\mathrm{IC}_{50}$ was determined empirically and required further refinement to get an absolute.

## Procedure for the $[\mathbf{1 + 2 + 1 + 2 ] - m e c h a n i s m ~ s t u d i e s ~ ( T a b l e ~ 2 3 ) ~}$

The reagents were reacted in the order shown in the table, using 1 mL of $\mathrm{CDCl}_{3}$ as solvent, where 1 Equiv. corresponds to 1 mmol of reagent, and 2 Equiv. corresponds to 2 mmol of reagent. The reactions were monitored by ${ }^{1} \mathrm{H}$ NMR analysis over time.

## Procedure for the $[1+2+1+2]$-cyclisation attempts using different enones (Table

 24)To 4-methoxy-3-buten-2-one ( $0.102 \mathrm{~mL}, 1 \mathrm{mmol}$ ), benzylamine ( $0.109 \mathrm{~mL}, 1 \mathrm{mmol}$ ) and $p$-nitrobenzaldehyde $(0.151 \mathrm{~g}, 1 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1.5 \mathrm{~mL})$ was added $\mathrm{Sc}(\mathrm{OTf})_{3}$ ( $10 \mathrm{~mol} \%$ ) and the reaction mixture was stirred at rt . After $24-48 \mathrm{~h}$, an enone ( 1 mmol ) was added to the reaction mixture. The mixture was stirred at rt and monitored via TLC and ${ }^{1} \mathrm{H}$ NMR analysis.

## Procedure for the triflic acid reaction (Equation 37)

To imine 243 ( $0.262 \mathrm{~g}, 2 \mathrm{mmol}$ ) and methyl vinyl ketone ( $0.162 \mathrm{~mL}, 2 \mathrm{mmol}$ ) in $\mathrm{CDCl}_{3}(1.5 \mathrm{~mL})$ was slowly added triflic acid $(0.177 \mathrm{~mL}, 2 \mathrm{mmol})$ at $-70{ }^{\circ} \mathrm{C}$. The reaction mixture was left to warm to rt overnight and monitored by ${ }^{1} \mathrm{H}$ NMR analysis.

## Procedure for the Lewis acid screening in the $\mathbf{R}=\mathbf{H}[4+2]$-cyclisation (Table 26)

To a Lewis acid ( $20 \mathrm{~mol} \%$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added imine $243(0.033 \mathrm{~g}$, $0.25 \mathrm{mmol})$ and methyl vinyl ketone ( $0.021 \mathrm{~mL}, 0.25 \mathrm{mmol}$ ) and the reaction mixtures were left to stir at rt for 24 h . The LCMS of the crude reaction mixtures were obtained, and the crude ${ }^{1} \mathrm{H}$ NMR spectra of those deemed to give the most promising results were obtained too.

## Procedure for the synthesis of piperidinone 433 (Table 27)

To imine 243 ( $0.131 \mathrm{~g}, 1 \mathrm{mmol}$ ) and methyl vinyl ketone ( $0.081 \mathrm{~mL}, 1 \mathrm{mmol}$ ) in solvent ( 1 mL ) was added condition A (Lewis acid). The reaction mixture was stirred at rt overnight prior to addition of condition B (base in excess). The reaction mixture was subsequently stirred at rt overnight, and if quenched with aqueous base ( 5 mL ), the mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$ with the combined organics dried
$\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The reaction mixtures were purified by silica gel chromatography.

Procedure for the [2+4]-methyl vinyl ketone cyclisation attempts using different imines (Table 30)

To an imine ( 1 mmol ) and methyl vinyl ketone ( $0.081 \mathrm{~mL}, 2 \mathrm{mmol}$ ) in $\mathrm{CDCl}_{3}$ $(1.5 \mathrm{~mL})$ was added $\operatorname{In}(\mathrm{OTf})_{3}(40 \mathrm{~mol} \%)$ and the mixtures were stirred at rt . After $12 \mathrm{~h}, 20 \%(\mathrm{aq}) \mathrm{NaOH}(5 \mathrm{~mL})$ was added to the reaction mixtures and these were monitored via TLC and ${ }^{1} \mathrm{H}$ NMR analysis.

## Procedure for reacting 243, 164 and 350 together (Equation 40)

To imine $243(0.131 \mathrm{~g}, 1 \mathrm{mmol})$ and $\mathrm{Yb}(\mathrm{OTf})_{3}(0.124 \mathrm{~g}, 0.2 \mathrm{mmol})$ in $\mathrm{CHCl}_{3}$ $(1.5 \mathrm{~mL})$ under argon was added methyl vinyl ketone 164 ( $0.081 \mathrm{~mL}, 1 \mathrm{mmol}$ ). After stirring the reaction mixture for $1 \mathrm{~h}, 4$-methoxy-3-buten-2-one 350 ( 0.102 mL , 1 mmol ) was added to the mixture and stirred overnight. Purification by silica gel chromatography ( $1: 1 \mathrm{EtOAc}:$ hexane, to $100 \%$, EtOAc, as eluent) afforded 433 as an beige oil ( $0.043 \mathrm{mg}, 21 \%$ ). Relative to this value, the crude ${ }^{1} \mathrm{H}$ NMR showed the presence of 432 ( $40 \%$ ) and 350 ( $>99 \%$ ).

## Procedure for the reaction between 456 and catechol borane (Scheme 67)

$456(0.131 \mathrm{~g}, 1.5 \mathrm{mmol})$ and catechol borane $(0.176 \mathrm{~g}, 1.5 \mathrm{mmol})$ were heated at $100{ }^{\circ} \mathrm{C}$ whilst stirring. After 5 h , the reaction mixture was cooled to rt and monitored by ${ }^{1} \mathrm{H}$ NMR analysis.

## Procedure for the hydroboration using IPC borane (Scheme 69)

To $(R)$-alpine-boramine ( $0.415 \mathrm{~g}, 1 \mathrm{mmol}$ ) in dry THF ( 2 mL ) under nitrogen was added $\mathrm{Et}_{2} \mathrm{O} \cdot \mathrm{BF}_{3}(0.25 \mathrm{~mL}, 2 \mathrm{mmol})$ and stirred at rt . Within an hour, a precipitate had formed. $456(0.211 \mathrm{~g}, 1 \mathrm{mmol})$ was added to the reaction mixture at $0{ }^{\circ} \mathrm{C}$, and the mixture was allowed to warm to rt overnight. Acetaldehyde ( $0.28 \mathrm{~mL}, 5 \mathrm{mmol}$ ) was added to the reaction mixture at $0^{\circ} \mathrm{C}$ and the reaction mixture was left to stir to rt . The mixture was subsequently concentrated in vacuo, treated with 6 N (aq) $\mathrm{HCl}(5 \mathrm{~mL})$ and stirred at $50^{\circ} \mathrm{C}$. After 2 h , the mixture was cooled to rt , washed with diethyl ether $(2 \times 10 \mathrm{~mL})$ and concentrated in vacuo. The residue was re-dissolved in water $(1 \mathrm{~mL})$,
toluene ( 5 mL ) was added, and the mixture was concentrated in vacuo. Azeotroping with toluene was repeated $(3 \times 5 \mathrm{~mL})$ to afford a brown solid $(0.62 \mathrm{~g})$.

Procedure for reaction attempts between imine 243 and 4-methoxy-3-buten-2one using different organocatalysts (Table 32)

To an organocatalyst HCl salt ( $20 \mathrm{~mol} \%$ ) and triethylamine ( $20 \mathrm{~mol} \%$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 1 mL ) was added imine $243(0.131 \mathrm{~g}, 1 \mathrm{mmol}$ ) and 4-methoxy-3-buten-2-one $(0.204 \mathrm{~mL}, 2 \mathrm{mmol})$. The reaction mixture was stirred at rt for 2 h and monitored by LCMS ands TLC analysis.

Procedure for the unsuccessful Lewis acid catalysed attempt of ring 496 (Table 33, entry 1)

To $N$-benzylidenebenzenesulfonamide ( $0.491 \mathrm{~g}, 2 \mathrm{mmol}$ ), $\mathrm{Yb}(\mathrm{OTf})_{3}(0.248 \mathrm{~g}$, $0.4 \mathrm{mmol})$ and $4 \AA$ molecular sieves in $\mathrm{CHCl}_{3}(2 \mathrm{~mL})$ under nitrogen was added Danishefsky's diene ( $0.488 \mathrm{~mL}, 2.5 \mathrm{mmol}$ ) dropwise. The reaction mixture was left to stir at rt.

Procedure for the unsuccessful Lewis acid and thermal catalysed attempt of ring 496 (Table 33, entry 3)

To $N$-benzylidenebenzenesulfonamide ( $0.491 \mathrm{~g}, 2 \mathrm{mmol}$ ) and $\mathrm{Sc}(\mathrm{OTf})_{3}(0.098 \mathrm{~g}$, 0.2 mmol ) in toluene ( 2 mL ) under nitrogen was added Danishefsky's diene $(0.488 \mathrm{~mL}, 2.5 \mathrm{mmol})$ dropwise. The reaction mixture was left to stir at $100{ }^{\circ} \mathrm{C}$ overnight.

## Procedure for Table 34 and Table 35 using imine 495

To an organocatalyst HCl salt ( $20 \mathrm{~mol} \%$ ) and triethylamine ( $20 \mathrm{~mol} \%$ ) in solvent ( 2 mL ) was added $N$-benzylidenebenzenesulfonamide ( $0.246 \mathrm{~g}, 1 \mathrm{mmol}$ ) and enone ( 1 mmol ). The reaction mixtures were stirred at the given temperatures and monitored by LCMS analysis.

## Procedure for the aldol reactions (Table 36)

To $p$-nitrobenzaldehyde ( $0.151 \mathrm{~g}, 1 \mathrm{mmol}$ ) and organocatalyst ( $20 \mathrm{~mol} \%$ ) [and triethylamine ( $20 \mathrm{~mol} \%$ ) if using the salt of the organocatalyst] in solvent ( 1 mL ) was
added ketone ( 1 mmol ). The reaction mixtures were stirred at rt and monitored via TLC analysis.

## Procedure for the Mannich reaction between imine 243 and acetone (Equation

 46)To imine 243 ( $0.131 \mathrm{~g}, 1 \mathrm{mmol}$ ) and acetone ( $0.73 \mathrm{~mL}, 1 \mathrm{mmol}$ ) in acetonitrile ( 1 mL ) was added L-proline ( $20 \mathrm{~mol} \%$ ). The reaction mixture was stirred at rt and monitored via TLC analysis.

## Procedure for an organocatalysed Mannich reaction attempt (Equation 49)

To $473(0.04 \mathrm{~g}, 0.2 \mathrm{mmol})$ and triethylamine ( $0.028 \mathrm{~mL}, 0.2 \mathrm{mmol}$ ) in toluene ( 1 mL ) was added acetophenone ( $0.117 \mathrm{~mL}, 1 \mathrm{mmol}$ ) and N -benzylidenebenzenesulfonamide ( $0.246 \mathrm{~g}, 1 \mathrm{mmol}$ ). The reaction mixture was flushed with nitrogen and stirred at rt . After 48 h , the temperature was raised to $70^{\circ} \mathrm{C}$.

## Procedure for the Michael reaction using methyl vinyl ketone (Equation 50 and

## Equation 51)

To dibenzylamine ( $0.59 \mathrm{~g}, 3.0 \mathrm{mmol}$ ) and a boronic acid catalyst ( $20 \mathrm{~mol} \%$ ) [and triethylamine ( $20 \mathrm{~mol} \%$ ) if the aminoboronic acid catalyst 477 was used] dissolved in water ( 3 mL ) was added methyl vinyl ketone ( $0.27 \mathrm{~mL}, 3.3 \mathrm{mmol}$ ) and the reaction mixture was stirred at rt overnight. The reaction mixture was extracted with EtOAc $(3 \times 10 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$, concentrated in vacuo and purified by silica gel chromatography (4:1, petroleum ether:diethyl ether, as eluent).

## Procedure for the Monitoring of the Michael Reaction (Table 37)

To additive $\mathrm{A}(10 \mathrm{~mol} \%)$ and additive $\mathrm{B}(10 \mathrm{~mol} \%)$ dissolved in $\mathrm{CDCl}_{3}(0.6 \mathrm{~mL})$ was added dibenzylamine ( $0.115 \mathrm{~mL}, 0.60 \mathrm{mmol}$ ) and methyl vinyl ketone ( 0.054 mL , $0.66 \mathrm{mmol})$. The reaction mixture was monitored by ${ }^{1} \mathrm{H}$ NMR every 0.5 h until the reaction had gone to completion.

## Procedure for the Gilman titration method ${ }^{212}$

Titration 1: To distilled water 427 ( 20 mL ) was added sec-BuLi $526(0.5 \mathrm{~mL})$ and phenolphthalein indicator (3 drops). This was titrated against 0.1 M (aq) HCl $(8.6 \mathrm{~mL})$ until complete disappearance of the pink colour.

Titration 2: To 1,2-dibromoethane $\mathbf{5 3 0}(0.2 \mathrm{~mL})$ in diethyl ether ( 3 mL ) was added at rt sec-BuLi $526(0.5 \mathrm{~mL})$ and the solution was stirred vigorously at rt for 5 min . The reaction mixture was diluted with distilled water $527(20 \mathrm{~mL})$, phenolphthalein indicator added (2-3 drops) and titrated against $0.1 \mathrm{M}(\mathrm{aq}) \mathrm{HCl}(2.3 \mathrm{~mL})$ with vigorous stirring until the end point was reached (complete disappearance of the pink colour) (Table 38).

Table 38. Example results from the Gilman double titration procedure.

| $\mathrm{c}(\mathrm{HCl})=0.1 \mathrm{M}$ | $\begin{gathered} \mathrm{v}(\mathrm{HCl})_{1}=8.6 \\ \mathrm{~mL} \end{gathered}$ | $\mathrm{v}(\mathrm{HCl})_{2}=2.3 \mathrm{~mL}$ |
| :---: | :---: | :---: |
| $\begin{aligned} \mathrm{v}(\mathrm{HCl})_{\text {eff }} & = \\ & = \end{aligned}$ | $\begin{aligned} & \mathrm{v}(\mathrm{HCl})_{1}-\mathrm{v}(\mathrm{HCl})_{2} \\ & 8.6 \mathrm{~mL}-2.3 \mathrm{~mL} \end{aligned}$ | $=6.3 \mathrm{~mL}$ |
| $\begin{aligned} c(s e c-B u L i) & = \\ & = \end{aligned}$ | $\begin{aligned} & \left(\mathrm{v}(\mathrm{HCl})_{1} \times \mathrm{v}(\mathrm{HCl})_{2}\right. \\ & (6.3 \times 0.1) / 0.5 \end{aligned}$ | $\begin{aligned} & / v_{\text {sec-BuLi }}(\text { aliquot }) \\ & =1.26 \mathrm{M} \end{aligned}$ |
| Residual base $=$ | $\begin{aligned} & \mathrm{v}(\mathrm{HCl})_{\text {eff }} / \mathrm{v}(\mathrm{HCl})_{1} \\ & 2.3 / 8.6 \times 100 \end{aligned}$ | $\begin{aligned} & \times 100 \\ & =27 \% \end{aligned}$ |
| Hence, residual base | $\begin{aligned} & =27 \% \text { of } 1.26 \mathrm{M} \\ & =0.34 \mathrm{M} \end{aligned}$ |  |
| Hence, effective sec-BuLi base | $\begin{aligned} & =1.26 \mathrm{M}-0.34 \mathrm{M} \\ & =0.9 \mathrm{M} \end{aligned}$ |  |

## Procedure for the single titration method ${ }^{213}$

To 1,3-diphenylacetone $p$-tosylhydrazone $\mathbf{5 3 3}$ ( $197 \mathrm{mg}, 0.53 \mathrm{mmol}$ ) under nitrogen at rt was added dry THF ( 4 mL ). Whilst stirring, the reaction mixture was titrated against sec-BuLi 526 ( 0.59 mL ) until the end point was reached (orange-red in colour) (Table 39).

Table 39. Example results from the single titration procedure.

```
\begin{tabular}{c|l}
\hline m (hydrazone) \(=0.00053 \mathrm{~mol}\) & \(\mathrm{v}(\mathrm{HCl})=0.59 \mathrm{~mL}\)
\end{tabular}
    Hence,
    Molarity of sec-BuLi \(=1000 \times \mathrm{m}\) (hydrazone) \(/ \mathrm{v}(\mathrm{HCl})\)
        \(=0.53 / 0.59\)
        \(=0.9 \mathrm{M}\)
```

## Procedure for drying THF

To THF ( 1000 mL ) and benzophenone ( 4 spatulas) was slowly added sodium ( $5 / 6$ small pieces). The mixture was stirred to reflux under argon. The mixture turned from colourless to blue, to deep blue, and finally to a deep purple when all of the THF was dry.

### 5.3 Synthetic Procedures

## 1-Methoxy-3-trimethylsiloxy-1,3-butadiene ${ }^{15}$

4

Triethylamine ( $4.18 \mathrm{~mL}, 30 \mathrm{mmol}$ ) was added to a stirred $1 \mathrm{M} \mathrm{ZnCl} 2_{2}$ solution in diethyl ether ( $0.40 \mathrm{~mL}, 0.4 \mathrm{mmol}$ ) under nitrogen. After 2 h the resulting suspension was treated with 4-methoxy-3-buten-2-one ( $1.33 \mathrm{~mL}, 13 \mathrm{mmol}$ ) in diethyl ether $(6.5 \mathrm{~mL})$ followed by chlorotrimethylsilane ( $3.30 \mathrm{~mL}, 26 \mathrm{mmol}$ ). The reaction mixture was stirred at $40{ }^{\circ} \mathrm{C}$ overnight, cooled to rt , diluted with diethyl ether $(50 \mathrm{~mL})$, filtered through an alumina pad and concentrated in vacuo. Purification by distillation under reduced pressure $\left(32^{\circ} \mathrm{C}, 0.5 \mathrm{mbar}\right)$ afforded 4 as a colourless liquid $(1.46 \mathrm{~g}, 65 \%):{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 6.82(\mathrm{~d}, J=12.4,1 \mathrm{H}, H c), 5.34(\mathrm{~d}, J=$ 12.4, 1H, $H b$ ), $4.10\left(\mathrm{~s}, 1 \mathrm{H}, H a_{t r a n s}\right), 4.06\left(\mathrm{~s}, 1 \mathrm{H}, H a_{c i s}\right), 3.57(\mathrm{~s}, 3 \mathrm{H}, H d), 0.22(\mathrm{~s}, 9 \mathrm{H}$, He) ppm; ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 154.1$ (s, Cf), 150.5 (d, Cc), 103.3 (d, Cb), $91.2(\mathrm{t}, C a), 56.5(\mathrm{~d}, C d), 0.1(\mathrm{~d}, C e)$; IR $v_{\max }$ (neat) $1652 \mathrm{~cm}^{-1}$; LRMS (TOF ES+), $173.10[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{8} \mathrm{H}_{16} \mathrm{O}_{2} \mathrm{Si}+\mathrm{H}^{+}$, 173.0992; found 173.0990. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{214}$

## 2,2-Dimethoxyethylidene-4-methyloxyaniline ${ }^{61}$

To $p$-anisidine ( $1.23 \mathrm{~g}, 10 \mathrm{mmol}$ ) and $3 \AA$ molecular sieves ( 10.0 g ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(40 \mathrm{~mL})$ was added dimethoxyacetaldehyde $(60 \%$ solution in water) $(2.60 \mathrm{~g}$, 15 mmol ) and the reaction mixture was stirred at rt overnight. The mixture was filtered and concentrated in vacuo to give a crude oil containing 75 and dimethoxyacetaldehyde. The mixture was distilled using a Kugelrohr $\left(100{ }^{\circ} \mathrm{C}\right.$, 1 mbar) to remove the aldehyde from the product, thus affording 75 as a red oil ( $1.97 \mathrm{~g}, 94 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.72(\mathrm{dd}, J=4.3,1.0 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Hc}), 7.13$ (d, $J=8.9 \mathrm{~Hz}, 2 \mathrm{H}, H d), 6.87(\mathrm{~d}, J=8.9 \mathrm{~Hz}, 2 \mathrm{H}, H e), 4.86(\mathrm{dd}, J=4.3,1.0 \mathrm{~Hz}, 1 \mathrm{H}$, $H b), 3.78(\mathrm{~d}, J=1.3 \mathrm{~Hz}, 3 \mathrm{H}, H f), 3.46(\mathrm{~d}, J=1.0 \mathrm{~Hz}, 6 \mathrm{H}, H a) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( 101 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 158.8(\mathrm{~s}, C h), 158.2(\mathrm{~d}, C c), 143.3$ ( $\mathrm{s}, C g$ ), 122.3 (d, Cd), 114.4 (d, $C e), 103.3$ (d, Cb), 55.5 (d, Cf), 54.1 (d, Ca); IR $v_{\text {max }}$ (neat) 2834 (OMe), 1744 (N=C), $1505(\mathrm{Ar}) \mathrm{cm}^{-1}$; LRMS (TOF ES + ), $232.1[\mathrm{M}+\mathrm{Na}]^{+}, 210.1[\mathrm{M}+\mathrm{H}]^{+}, 178.1$; HRMS (TOF ES+), calculated for $\mathrm{C}_{11} \mathrm{H}_{15} \mathrm{NO}_{3}+\mathrm{H}^{+}, 210.1130$; found 210.1141. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{61}$

Ethyl $\boldsymbol{N}$-(p-methoxyphenyl)iminoacetate ${ }^{215}$

155

To ethyl glyoxylate solution ( $50 \%$ in toluene) $(5.11 \mathrm{~g}, 25 \mathrm{mmol})$ and $3 \AA$ molecular sieves ( 5 g ) was slowly added a 1 M solution of $p$-anisidine ( $3.08 \mathrm{~g}, 25 \mathrm{mmol}$ ) in toluene ( 25 mL ) over 30 min . The reaction mixture was stirred at rt overnight, washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, filtered and concentrated in vacuo. The oil was filtered to separate the precipitate that was formed, and the filtrate was distilled using a Kugelrohr $\left(175{ }^{\circ} \mathrm{C}\right.$, $0.5 \mathrm{mbar})$ for 2 h to afford $\mathbf{1 5 5}$ as a thick orange oil ( $1.18 \mathrm{~g}, 23 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( 400 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 7.94(\mathrm{~s}, 1 \mathrm{H}, H c), 7.38-7.34(\mathrm{~m}, 2 \mathrm{H}, H d), 6.95-6.91(\mathrm{~m}, 2 \mathrm{H}, \mathrm{He}), 4.41$ (q, $J=7.1 \mathrm{~Hz}, 2 \mathrm{H}, H b), 3.84(\mathrm{~s}, 3 \mathrm{H}, H f), 1.40(\mathrm{t}, J=7.1 \mathrm{~Hz}, 3 \mathrm{H}, H a) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 163.8$ (s, Cg), 160.7 (s, Ci), 148.2 (d, Cc), 141.6 (s, Ch), 123.7
(d, Cd), 114.7 (d, Ce), $62.0(\mathrm{t}, C b), 55.7(\mathrm{~d}, C f), 14.4$ (d, Ca); IR $v_{\max }$ (neat) 2835 (OMe), $1736(\mathrm{~N}=\mathrm{C}), 1714(\mathrm{C}=\mathrm{O}), 1505(\mathrm{Ar}) \mathrm{cm}^{-1}$; LRMS (TOF ES+), 230.1 $[\mathrm{M}+\mathrm{Na}]^{+}, 208[\mathrm{M}+\mathrm{H}]^{+}, 134.1,124.1 ;$ HRMS (TOF ES+), calculated for $\mathrm{C}_{11} \mathrm{H}_{13} \mathrm{NO}_{3}+\mathrm{H}^{+}$, 208.0974; found 208.0978. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{216}$

## 3,4-Dihydroisoquinoline ${ }^{217}$

243

Formamide $337(1.00 \mathrm{~g}, 6.7 \mathrm{mmol})$ and polyphosphoric acid ( 6 g ) were heated to $160{ }^{\circ} \mathrm{C}$ overnight whilst stirring. The reaction mixture was poured into ice water and stirred for 3 h . The mixture was basified with $20 \%$ (aq) $\mathrm{NaOH}(50 \mathrm{~mL}$ ), extracted with diethyl ether $(2 \times 50 \mathrm{~mL})$, the combined extracts were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford 243 as an orange oil $(0.736 \mathrm{~g}, 84 \%)$ : $R_{f .} 0.15$ (EtOAc, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $700 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.3$ (br s, $1 \mathrm{H}, H a$ ), $7.31(\mathrm{t}, J=7.3 \mathrm{~Hz}, 1 \mathrm{H}$, $H e), 7.26(\mathrm{t}, J=7.3 \mathrm{~Hz}, 1 \mathrm{H}, H f), 7.22(\mathrm{~d}, J=7.3 \mathrm{~Hz}, 1 \mathrm{H}, H g), 7.11(\mathrm{~d}, J=7.3 \mathrm{~Hz}$, $1 \mathrm{H}, H d), 3.73(\mathrm{t}, J=7.8 \mathrm{~Hz}, 2 \mathrm{H}, H b), 2.71(\mathrm{t}, J=7.8 \mathrm{~Hz}, 2 \mathrm{H}, H c) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 160.4$ (d, Ca), 136.4 ( $\left.\mathrm{s}, \mathrm{Ci}\right), 131.1$ (d, Ce), 128.5 ( $\left.\mathrm{s}, \mathrm{Ch}\right), 127.4$ (d, Cd), $127.2(\mathrm{~s}, C f), 127.1(\mathrm{~s}, C g), 47.4(\mathrm{t}, C b), 25.0(\mathrm{t}, C c) ;$ IR $v_{\max }(\mathrm{neat}) 1626$ $\mathrm{cm}^{-1}$; LRMS (TOF ES + ), 132.2 ( $100 \%$ ) $[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES + ), calculated for $\mathrm{C}_{9} \mathrm{H}_{9} \mathrm{~N}+\mathrm{H}^{+}, 132.08078$; found 132.08092. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{164,218}$

## 6,7-Dihydro-1H-pyrido[2,1-a]isoquinolin-2(11bH)-one ${ }^{219}$

To $246(0.131 \mathrm{~g}, 1.0 \mathrm{mmol})$ and $\mathrm{Yb}(\mathrm{OTf})_{3}(0.124 \mathrm{~g}, 0.2 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1.5 \mathrm{~mL})$ under argon was added Danishefsky's diene ( $0.240 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ) dropwise. The reaction mixture was stirred at rt for 4 h , quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(4 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$. The combined extracts were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (4:1, EtOAc:hexane, to $100 \%$, EtOAc, as eluent) afforded 244 as a pale orange solid ( $0.030 \mathrm{~g}, 15 \%$ ): m.p. $94-97{ }^{\circ} \mathrm{C}$; R R. 0.05 (2:1, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 7.29-7.17 (m, 4H, $H d+e+f+g), 7.16(\mathrm{dd}, J=7.4,0.9 \mathrm{~Hz}, H h), 5.08(\mathrm{dd}, J=7.4,0.9$ $\mathrm{Hz}, 1 \mathrm{H}, H i), 4.76(\mathrm{dd}, J=16.3,4.5 \mathrm{~Hz}, 1 \mathrm{H}, H a), 3.64(\mathrm{ddd}, J=12.2,5.1,2.3 \mathrm{~Hz}, 1 \mathrm{H}$, $H b_{\text {eq }}$ ), 3.45 (td, $J=12.2,3.2 \mathrm{~Hz}, 1 \mathrm{H}, H b_{a x}$ ), 3.16 (apparent ddd, $J=15.8,5.1,0.9 \mathrm{~Hz}$, $1 \mathrm{H}, H c$ ), 2.87-2.85 (m, 1H, Hj), 2.84-2.81 (m, 1H, Hc), 2.53 (t, $J=16.3 \mathrm{~Hz}, 1 \mathrm{H}, H j$ ) ppm; ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 192.8$ (s, Cm), 154.2 (d, Ch) 135.0 (s, Cl ), 133.5 ( $\mathrm{s}, C k$ ), 129.5 (d, $C d$ ), 127.3 (d, $C f$ ), 127.2 (d, $C e$ ), 125.7 (d, $C g$ ), 98.7 (d, $C i$ ), 56.7 (d, $C a), 49.8(\mathrm{t}, C j), 44.1(\mathrm{t}, C b), 30.4(\mathrm{t}, C c)$; IR $v_{\text {max }}\left(\right.$ (thin film) $1630,1586,1581 \mathrm{~cm}^{-1}$; LRMS (TOF ES+ + , 222.2 ( $100 \%$ ) [M+Na] ${ }^{+} 200.2$ ( $40 \%$ ) $[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{13} \mathrm{H}_{13} \mathrm{NO}+\mathrm{H}^{+}, 200.1075$; found 200.1079. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{84,220}$

First alternate procedure:
To $246(0.131 \mathrm{~g}, 1.0 \mathrm{mmol})$ and $3 \AA$ molecular sieves $(1 \mathrm{~g})$ under argon was added Danishefsky's diene ( $0.240 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ) dropwise. The reaction mixture was stirred at rt for 48 h , diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(25 \mathrm{~mL})$, filtered and concentrated in vacuo. Purification by silica gel chromatography (3:1, EtOAc:hexane, to $100 \%$, EtOAc, as eluent) afforded 244 as a pale orange solid ( $0.093 \mathrm{~g}, 47 \%$ ).

Second alternate procedure:
To 246 ( $0.131 \mathrm{~g}, 1.0 \mathrm{mmol}$ ), $\mathrm{CeCl}_{3}(0.049 \mathrm{~g}, 0.2 \mathrm{mmol})$, 2-ethyl-2-oxazoline ( $0.040 \mathrm{~mL}, 0.4 \mathrm{mmol}$ ) and $3 \AA$ molecular sieves ( 1 g ) under argon in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(1.5 \mathrm{~mL})$ was added Danishefsky's diene $(0.240 \mathrm{~mL}, 1.2 \mathrm{mmol})$ dropwise. The reaction mixture was stirred at rt for 48 h , quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(5 \mathrm{~mL})$, diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and brine $(10 \mathrm{~mL})$, filtered and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times$ $5 \mathrm{~mL})$. The combined extracts were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo.

Purification by silica gel chromatography (4:1, EtOAc:hexane, to $100 \%$, EtOAc, as eluent) afforded 244 as a pale orange solid ( $0.099 \mathrm{~g}, 49 \%$ ).

## 4,9-Dihydro-3H- $\boldsymbol{\beta}$-carboline ${ }^{221}$

246

To 339 ( $0.436 \mathrm{~g}, 2.3 \mathrm{mmol}$ ) at $0{ }^{\circ} \mathrm{C}$ was slowly added phosphorus(V) oxychloride $(4 \mathrm{~mL})$ and the reaction mixture was left to stir at rt . After 12 h , the mixture was quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(20 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$ and basified with $20 \%$ (aq) NaOH $(50 \mathrm{~mL})(\mathrm{pH}=14)$. The mixture was subsequently warmed to rt , diluted with water ( 100 mL ), extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 20 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford 246 as an orange solid ( $0.329 \mathrm{~g}, 84 \%$ ): m.p. $91-92{ }^{\circ} \mathrm{C}$ (lit. $92.0-93.5$ $\left.{ }^{\circ} \mathrm{C}\right)^{222} ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 9.06(\mathrm{~s}, 1 \mathrm{H}, H a), 7.53-7.49(\mathrm{~m}, 1 \mathrm{H}, H d), 7.45-$ $7.41(\mathrm{~m}, 1 \mathrm{H}, H g), 7.35-7.30(\mathrm{~m}, 1 \mathrm{H}, H f), 7.13-7.08(\mathrm{~m}, 1 \mathrm{H}, H e), 3.85(\mathrm{t}, J=9.0 \mathrm{~Hz}$, $2 \mathrm{H}, H b), 3.06(\mathrm{t}, J=9.0 \mathrm{~Hz}, 2 \mathrm{H}, H c) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{DMSO}$ ) $\delta 150.58(\mathrm{~d}$, $C a), 135.5$ (135.7)(s, Ck), 130.6 (s, Ch), 125.1 (127.4)(s, Cj), 122.6 (120.2)(d, Cf), 117.4 (118.6)(d, $C e), 117.0(118.5)(\mathrm{d}, C g), 111.4$ (112.7)(s, $C i), 110.4$ (111.4)(d, Cd), $42.5(47.1)(\mathrm{t}, ~ C b), 20.9(17.7)(\mathrm{t}, C c) ;$ LRMS (TOF ES+), 171.7 (90\%) $[\mathrm{M}+\mathrm{H}]^{+}, 144.4$ (100\%); HRMS (TOF ES + ), calculated for $\mathrm{C}_{11} \mathrm{H}_{10} \mathrm{~N}_{2}+\mathrm{H}^{+}$, 171.0922; found 171.0921. ## 2-Phenylethanamine ${ }^{231}$

335

An impure commercial sample of 2-phenylethylamine ( $15 \mathrm{~mL}, 124 \mathrm{mmol}$ ) was purified by distillation under vacuum ( $53 \mathrm{mbar}, 78^{\circ} \mathrm{C}$ ) to afford 335 as a colourless oil ( $13.04 \mathrm{~g}, 87 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.33-7.27(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Hb}), 7.24-7.17$ $(\mathrm{m}, 3 \mathrm{H}, H c+a), 2.97(\mathrm{t}, J=6.9 \mathrm{~Hz}, 2 \mathrm{H}, H e), 2.75(\mathrm{t}, J=6.9 \mathrm{~Hz}, 2 \mathrm{H}, H d), 1.18(\mathrm{br} \mathrm{s}$, $2 \mathrm{H}, \mathrm{N} H) \mathrm{ppm}$ (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta 1.18$ to disappear); ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 140.0$ (139.3) (s, Cf), 128.9 (128.6) (d, Cb), 128.3 (127.9) (d, $C c$ ), 126.3 (125.6) (d, $C a$ ), 43.7 (43.0) (t, Ce), 40.3 (39.6) (t, Cd); LRMS (TOF ES+), $122.4(100 \%)[\mathrm{M}+\mathrm{H}]^{+}, 105.6(55 \%)$; HRMS (FTMS ES + ), calculated for $\mathrm{C}_{8} \mathrm{H}_{11} \mathrm{~N}+\mathrm{H}^{+}$, 122.0970; found 122.0972; Anal. Calcd: C, 79.29, H, 9.15, N, 11.56, found: C, 73.80, $\mathrm{H}, 8.61, \mathrm{~N}, 11.82$. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{232}$

## $N$-Phenethylformamide ${ }^{233}$

337

2-Phenylethylamine $335(2.52 \mathrm{~mL}, 20 \mathrm{mmol})$ and ethyl formate ( $4.02 \mathrm{~mL}, 50 \mathrm{mmol}$ ) were stirred and heated to reflux $\left(60{ }^{\circ} \mathrm{C}\right)$ overnight. The reaction mixture was concentrated in vacuo and distilled by Kugelrohr distillation ( $180{ }^{\circ} \mathrm{C}, 2 \mathrm{mbar}$ ) to afford 337 as a colourless oil ( $2.472 \mathrm{~g}, 83 \%$ ): $R_{f .} 0.25$ (EtOAc, as eluent); ${ }^{1} \mathrm{H}$ NMR
( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 5: 1$ mixture $\{1 \mathrm{H}, H f[$ major isomer: $\delta 8.11$ (s), minor isomer: $\delta$ $7.90(\mathrm{~d}, J=11.9 \mathrm{~Hz})]\}, 7.34-7.28(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ar} H), 7.27-7.15(\mathrm{~m}, 3 \mathrm{H}, \mathrm{ArH}), 5.72(\mathrm{br} \mathrm{s}$, $1 \mathrm{H}, \mathrm{NH}$ ), 5:1 mixture $\{2 \mathrm{H}, \mathrm{He}$ [major isomer: $\delta 3.57(\mathrm{q}, J=6.8 \mathrm{~Hz})$, minor isomer: $\delta$ $3.47(\mathrm{~d}, J=6.7 \mathrm{~Hz})]\}, 5: 1$ mixture $\{2 \mathrm{H}, H d$ [major isomer: $\delta 2.84(\mathrm{t}, J=6.8 \mathrm{~Hz})$, minor isomer: $\delta 2.81(\mathrm{~d}, J=6.7 \mathrm{~Hz})$ ]\} ppm [addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta$ 7.90 to turn into a (s), the signal at $\delta 5.72$ to disappear, the signal at $\delta 3.57$ and 3.47 to turn into ( t with $J=6.9$ and 4.8 Hz respectively), and the signal at $\delta 2.84$ and 2.81 to turn into 2.87 and $2.82\left(\mathrm{t}\right.$ of $J=6.9$ and 6.8 Hz respectively)]; ${ }^{13} \mathrm{C}$ NMR ( 101 MHz , $\left.\mathrm{CDCl}_{3}\right) \delta$ (minor rotamer in brackets) 161.4 (164.6)(d, Cf), 138.6 (137.7)(s, Ar), 128.7 (128.8)(d, Ar), 128.6 (128.7)(d, Ar), 126.5 (126.8)(d, Ar), 39.2 (43.2)(t, $\left.\mathrm{CH}_{2} \mathrm{Ce}\right), 35.4$ (37.6)(t, Cd); IR $v_{\max }$ (neat) 3282, 3028, $1656(\mathrm{C}=\mathrm{O}) \mathrm{cm}^{-1}$; LRMS (TOF ES+), 172.2 ( $100 \%$ ) $[\mathrm{M}+\mathrm{Na}]^{+}, 150.2$ (24\%) $[\mathrm{M}+\mathrm{H}]^{+}$, 122.1; HRMS (TOF ES+), calculated for $\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{ON}+\mathrm{H}^{+}$, 150.09134; found 150.09150. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{164}$

## $N$-Formyltryptamine ${ }^{234}$

339

Ethyl formate ( 6 mL ) was added to tryptamine $(0.48 \mathrm{~g}, 3 \mathrm{mmol})$, and the reaction mixture was stirred at $60^{\circ} \mathrm{C}$. After 12 h , the mixture was cooled to rt and concentrated in vacuo. The mixture was subsequently diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(5 \mathrm{~mL})$ and washed with $1 \mathrm{M}(\mathrm{aq}) \mathrm{HCl}(5 \mathrm{~mL})$, sat. $\mathrm{K}_{\mathrm{z}} \mathrm{CO}_{3}(5 \mathrm{~mL})$ and brine ( 5 mL ). The organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford 339 as an off-colourless oil $(0.467 \mathrm{~g}$, $83 \%$ ): (3:1 major:minor rotamer, the minor shown in brackets): ${ }^{1} \mathrm{H}$ NMR ( 700 MHz , $\mathrm{CDCl}_{3}$ ) $\delta 8.13[7.92(\mathrm{~d}, J=12.3 \mathrm{~Hz})](\mathrm{s}, 1 \mathrm{H}, H h), 8.10(\mathrm{br} \mathrm{s}, 1 \mathrm{H}, H \mathrm{NC}=\mathrm{O}), 7.69$ (7.56)(d, $J=7.7 \mathrm{~Hz}, 1 \mathrm{H}, H e), 7.39$ (7.39)(d, $J=7.7 \mathrm{~Hz}, 1 \mathrm{H}, H b), 7.22$ (7.22)(t, $J=$ $7.7 \mathrm{~Hz}, 1 \mathrm{H}, H d), 7.14$ (7.15)(t, $J=7.7 \mathrm{~Hz}, 1 \mathrm{H}, H c), 7.06$ (7.04)(s, 1H, Ha), 5.59 (br s, $1 \mathrm{H}, \mathrm{N} H), 3.67(3.54)(\mathrm{q}, J=6.5 \mathrm{~Hz}, 2 \mathrm{H}, H g), 3.02(2.98)(\mathrm{t}, J=6.5 \mathrm{~Hz}, 2 \mathrm{H}) \mathrm{ppm}$ (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signals at $\delta 8.10$ and 5.59 to disappear, and the signals at
$\delta 7.92,3.67$ and 3.54 to change to a s, t and t respectively); ${ }^{13} \mathrm{C}$ NMR ( 101 MHz , $\left.\mathrm{CDCl}_{3}\right) \delta 161.3$ (164.6)(d, Ch), 136.6 (136.6)(s, Ck), 127.4 (127.0)(s, Cj), 122.5 (122.7)(d, Ca), 122.3 (122.6)(d, Cd), 119.8 (119.9)(d, Cc), 118.8 (118.5)(d, Ce), 112.8 (111.8)(s, $C i), 111.4$ (111.6)(d, $C b), 38.5$ (42.1)(t, $C g), 25.4$ (27.6)(t, $C f)$; IR $v_{\max } \mathrm{cm}^{-1}$; LRMS (TOF ES + ), 211.5 ( $100 \%$ ) $[\mathrm{M}+\mathrm{Na}]^{+}$; HRMS (TOF ES + ), calculated for $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{~N}_{2} \mathrm{O}+\mathrm{Na}^{+}, 211.0847$; found $211.0851 .{ }^{1} \mathrm{H}$ NMR properties were identical to that reported in the literature. ${ }^{165}$

## 1-Chloropiperidine ${ }^{235}$

341

To $N$-chlorosuccinimide ( $2.94 \mathrm{~g}, 22 \mathrm{mmol}$ ) in diethyl ether ( 100 mL ) was added dropwise piperidine $(1.98 \mathrm{~mL}, 20 \mathrm{mmol})$ and the reaction mixture was stirred at rt . After 3 h , the mixture was filtered, and the precipitate washed with diethyl ether $(25 \mathrm{~mL})$. The combined organics were subsequently washed with water $(3 \times 25 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford 341 as a colourless oil $(1.99 \mathrm{~g}$, $83 \%$ ): $R_{f .} 0.49$ (3:1, hexane:diethyl ether, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $700 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 3.70-2.60 (br m, 4H, Ha), 1.74-1.54 (m, 4H, Hb), 1.54-1.15 (br m, 2H, Hc) ppm; ${ }^{13} \mathrm{C}$ NMR ( $176 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 64.0(\mathrm{t}, \mathrm{Ca}), 27.6(\mathrm{t}, \mathrm{Cc}), 23.0(\mathrm{t}, \mathrm{Cb})$; IR $v_{\text {max }}$ (neat) 2940, 2830, 1442, 679 (N-Cl) $\mathrm{cm}^{-1}$; LRMS (EI+) 118.0 (100\%) [M-H] ${ }^{+} 119.0$ (50\%) [M], 120.0 (40\%), 121.0 ( $15 \%$ ); HRMS (EI-), calculated for $\mathrm{C}_{5} \mathrm{H}_{9} \mathrm{NCl}, 118.0418$; found 118.0420. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{167,236}$

## 4-Phenyl-3-buten-2-one ${ }^{237}$

347

To a stirred solution of benzaldehyde ( $10.61 \mathrm{~g}, 100 \mathrm{mmol}$ ), acetone ( 20 mL , 0.27 mmol ) and water ( 40 mL ) was added dropwise $5 \%(\mathrm{aq}) \mathrm{NaOH}(8 \mathrm{~mL})$ and the reaction mixture was stirred at $40^{\circ} \mathrm{C}$ for 4 h . The reaction mixture was diluted with EtOAc $(100 \mathrm{~mL})$ and the organics extracted with EtOAc $(3 \times 25 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford 347 as a yellow liquid ( $13.35 \mathrm{~g}, 91 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.55-7.51(\mathrm{~m}, 3 \mathrm{H}, H d+f), 7.50(\mathrm{~d}, J=16.3 \mathrm{~Hz}, 1 \mathrm{H}, H c), 7.40-$ $7.36(\mathrm{~m}, 2 \mathrm{H}, H e), 6.70(\mathrm{~d}, J=16.3 \mathrm{~Hz}, 1 \mathrm{H}, H b), 2.34(\mathrm{~s}, 3 \mathrm{H}, H a) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 198.4$ ( $\mathrm{s}, C g$ ), 143.4 (d, Cc), 134.5 ( s, Ch), 130.6 (d, Cf), 129.0 (d, $C e$ ), 128.3 (s, Cd), 127.2 (d, Cb), 27.6 (d, $C a$ ); IR $v_{\text {max }}($ neat $) 1666(\mathrm{C}=\mathrm{C}), 1608$ $(\mathrm{C}=\mathrm{O}) \mathrm{cm}^{-1}$; LRMS (TOF ES + ), $147.1[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES + ), calculated for $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}+\mathrm{H}^{+}, 147.0810$; found 147.0814. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{238,239}$

## trans-1-Phenyl-3-trimethylsilyloxybutadiene ${ }^{240}$

349

To a suspension of $\operatorname{zinc}($ II $)$ chloride $(0.2 \mathrm{~g}, 1.5 \mathrm{mmol})$ in triethylamine ( 15 mL , 108 mmol ) was added a solution of 4-phenyl-3-but-2-one ( $7.3 \mathrm{~g}, 50 \mathrm{mmol}$ ) in toluene $(15 \mathrm{~mL})$, followed by chlorotrimethylsilane ( $13 \mathrm{~mL}, 100 \mathrm{mmol}$ ) and the reaction mixture was stirred at $40^{\circ} \mathrm{C}$ overnight. The reaction mixture was cooled to rt and diluted with diethyl ether ( 100 mL ). The mixture was filtered, concentrated in vacuo
and distilled at reduced pressure ( $92{ }^{\circ} \mathrm{C}, 1 \mathrm{mbar}$ ) to afford 349 as a yellow liquid ( $6.10 \mathrm{~g}, 56 \%$ ): $R_{f .} 0.57$ (2:1, hexane:EtOAc as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 7.43-7.36 (m, 2H, ArH), 7.33-7.29 (m, 2H ArH), 7.24-7.20 (m, 1H ArH), 6.81 (d, $J=$ $15.7 \mathrm{~Hz}, 1 \mathrm{H}, H c$ ), $6.59(\mathrm{~d}, ~, J=15.7 \mathrm{~Hz}, 1 \mathrm{H}, H b), 4.47\left(\mathrm{br} \mathrm{s}, 1 \mathrm{H}, H a_{Z}\right), 4.43(\mathrm{br} \mathrm{s}, 1 \mathrm{H}$, $\left.H a_{E}\right), 0.28(\mathrm{~s}, 9 \mathrm{H}, H d) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 155.2$ ( $\mathrm{s}, \mathrm{Ce}$ ), 136.9 (s, Ar), 129.3 (d, Cc), 128.7 (d, Ar), 127.8 (d, Ar para ), 126.9 (d, Ar), 126.5 (d, Cb), 97.2 $(\mathrm{t}, \mathrm{Ca}), 0.2(\mathrm{~d}, C d) ;$ IR $v_{\max }$ (neat) $1670,(\mathrm{C}=\mathrm{C}), 1610(\mathrm{Ar}), 1252\left(\mathrm{SiCH}_{3}\right) \mathrm{cm}^{-1} ;$ LRMS (GC EI), 218.1 (68\%) [M], 203.1, 128.1, 127.1, 75.1 (100\%), 73.1; HRMS (TOF $\mathrm{AP}+$ ), calculated for $\mathrm{C}_{13} \mathrm{H}_{18} \mathrm{OSi}^{+} \mathrm{H}^{+}$, 219.1205; found 219.1212. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{240,241}$

## 4-(p-Methoxy)-3-buten-2-one ${ }^{242}$

353

To $p$-methoxybenzaldehyde ( $12.15 \mathrm{~mL}, 100 \mathrm{mmol}$ ), acetone ( $20 \mathrm{~mL}, 272 \mathrm{mmol}$ ), and water ( 40 mL ) was slowly added $5 \%(\mathrm{aq}) \mathrm{NaOH}(8 \mathrm{~mL})$ and the reaction mixture was stirred at $40{ }^{\circ} \mathrm{C}$ overnight. The reaction mixture was filtered, the solid dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to give 353 as a pale yellow solid ( $15 \mathrm{~g}, 88 \%$ ): m.p. $72-73{ }^{\circ} \mathrm{C}$ (lit. $\left.72-72.5{ }^{\circ} \mathrm{C}\right)^{243} ; R_{f .} 0.27$ (2:1, hexane:EtOAc as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.52-7.48(\mathrm{~m}, 2 \mathrm{H}, H d), 7.48(\mathrm{~d}, J=16.2 \mathrm{~Hz}$, $1 \mathrm{H}, H c), 6.94-6.90(\mathrm{~m}, 2 \mathrm{H}, H e), 6.61(\mathrm{~d}, J=16.2 \mathrm{~Hz}, 1 \mathrm{H}, H b), 3.85(\mathrm{~s}, 3 \mathrm{H}, H f), 2.36$ (s, 3H, Ha) ppm; ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 198.6$ (s, Cg ), 161.8 (s, Ci), 143.4 (d, Cc), 130.1 (d, Cd), 127.2 (s, Ch), 125.2 (d, Cb), 114.6 (d, Ce), 55.6 (d, Cf), 27.6 (d, Ca); IR $v_{\text {max }}$ (neat) 2840, (OMe), 1656 (C=C), 1599 (C=O), 1510 (Ar) $\mathrm{cm}^{-1}$; LRMS (TOF ES+), 199.1 ( $100 \%$ ) $[\mathrm{M}+\mathrm{Na}]^{+}, 177.2[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{O}_{2}+\mathrm{H}^{+}, 177.09101$; found 177.09097. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{238,244}$

## 4-(p-Nitrophenyl)-3-buten-2-one ${ }^{245}$

355

To a stirred solution of $p$-nitrobenzaldehyde ( $3.00 \mathrm{~g}, 19.9 \mathrm{mmol}$ ) in acetone ( 17.8 mL , $0.68 \mathrm{~mol})$ was added dropwise $0.1 \mathrm{M}(\mathrm{aq}) \mathrm{NaOH}(200 \mathrm{~mL})$ and the reaction mixture was stirred at rt for 1.5 h . The reaction mixture was filtered, the filtrate diluted with EtOAc ( 120 mL ) and the organics extracted with EtOAc $(3 \times 100 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude was purified by silica gel chromatography ( $2: 1$, hexane:EtOAc, as eluent) to afford $\mathbf{3 5 5}$ as a yellow solid $(1.57 \mathrm{~g}, 41 \%):$ m.p. $105-106^{\circ} \mathrm{C}\left(\text { lit. } 104-105^{\circ} \mathrm{C}\right)^{246} ; R_{f} .0 .38(1: 1$, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.28-8.24(\mathrm{~m}, 2 \mathrm{H}, \mathrm{He})$, 7.71-7.68 (m, 2H, Hd), $7.53(\mathrm{~d}, J=16.3 \mathrm{~Hz}, 1 \mathrm{H}, H c), 6.82(\mathrm{~d}, J=16.3 \mathrm{~Hz}, 1 \mathrm{H}, H b), 2.40(\mathrm{~s}, 3 \mathrm{H}, H a) \mathrm{ppm} ;$ ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 197.6$ ( $\mathrm{s}, C f$ ), 148.8 (s, Ch), 140.8 (s, Cg), 140.2 (d, $C c), 130.5(\mathrm{~d}, C b), 128.9(\mathrm{~d}, C d), 124.4(\mathrm{~d}, C e), 28.2(\mathrm{~d}, C a) ;$ IR $v_{\max }$ (neat) 1690 (C=C), 1594 ( $\mathrm{C}=\mathrm{O}$ ), 1511 (Ar), $1342\left(\mathrm{NO}_{2}\right) \mathrm{cm}^{-1}$; LRMS (TOF ES+), 192.1 (100\%) $[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{10} \mathrm{H}_{9} \mathrm{NO}_{3}+\mathrm{H}^{+}$, 192.0661; found 192.0672. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{247}$

## 1-Allyl-2,6-diphenyl-piperidin-4-one ${ }^{94}$

To $324(0.50 \mathrm{~g}, 3.44 \mathrm{mmol})$ in $\mathrm{MeOH}(2 \mathrm{~mL})$ was added 4-phenyl-3-buten-2-one $(2.91 \mathrm{~g}, 13.77 \mathrm{mmol})$ and L-proline ( $79 \mathrm{mg}, 0.2 \mathrm{mmol}$ ). The reaction mixture was stirred at rt overnight. The mixture was concentrated in vacuo and purification by silica gel chromatography ( $8: 1$, hexane:EtOAc, as eluent) gave a mixture of $\mathbf{3 5 7}$ and benzaldehyde ( 433 mg ). This was dissolved in EtOAc ( 2 mL ) and washed with $5 \%$ (aq) $\mathrm{HCl}(3 \times 1 \mathrm{~mL}) .5 \%(\mathrm{aq}) \mathrm{NaOH}(3 \mathrm{~mL})$ was added to the combined aqueous layers and the product extracted using EtOAc ( $3 \times 5 \mathrm{~mL}$ ), dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to give 357 as a yellow/orange oil ( $50 \mathrm{mg}, 43 \%$ ): $R_{f .} 0.61$ (1:1, EtOAc:hexane as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 7.47-7.44 (m, $4 \mathrm{H}, \mathrm{ArH}$ ), 7.39-7.36 (m, 4H, ArH), 7.29 (tt, $J=2.0,7.0 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{He}$ ), 5.75 (ddt, $J=17.0,10.0$, $7.0 \mathrm{~Hz}, 1 \mathrm{H}, H g), 5.03\left(\mathrm{dd}, J=10.0,2.0 \mathrm{~Hz}, 1 \mathrm{H}, H h_{\text {trans }}\right), 4.67(\mathrm{dd}, J=17.0,2.0 \mathrm{~Hz}$, $1 \mathrm{H}, H h_{\text {ciss }}$ ), 3.94 (dd, $J=12.0,3.0 \mathrm{~Hz}, 2 \mathrm{H}, H a$ ), 2.98 (d, $J=7.0 \mathrm{~Hz}, 2 \mathrm{H}, H f$ ), 2.75$2.84\left(\mathrm{~m}, 2 \mathrm{H}, H b_{\text {trans }}\right), 2.53-2.48\left(\mathrm{~m}, 2 \mathrm{H}, H b_{c i s}\right) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 207.4 (s, $C i$ ), 142.6 (s, Ar), 130.7 (d, $C g$ ), 128.8 (d, Ar), 127.7 (d, Ce), 127.4 (d, Ar), $119.6(\mathrm{t}, C h), 64.6(\mathrm{~d}, C a), 51.29(\mathrm{t}, C f), 50.93(\mathrm{t}, C b) ; \mathrm{IR} v_{\max }($ thin film $) 1717(\mathrm{C}=\mathrm{O})$ $\mathrm{cm}^{-1}$; LRMS (TOF ES + ), $292.2[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES + ), calculated for $\mathrm{C}_{20} \mathrm{H}_{21} \mathrm{NO}+\mathrm{H}^{+}, 292.1696$; found 292.1712. Both ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR properties were identical to those reported in the literature. ${ }^{94}$

## (Z)-4-(Allylamino)but-3-en-2-one ${ }^{248}$

358

To $324(0.145 \mathrm{~g}, 1.0 \mathrm{mmol})$ in $\mathrm{MeOH}(0.5 \mathrm{~mL})$ was added 4-methoxy-3-buten-2-one $(0.255 \mathrm{~mL}, 2.5 \mathrm{mmol})$ and $\mathrm{Sc}(\mathrm{OTf})_{3}(0.049 \mathrm{~g}, 0.1 \mathrm{mmol})$. The reaction mixture was flushed with argon and stirred at rt for 2 days, washed with sat. (aq) $\mathrm{NaHCO}_{3}(5 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 7 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (1:9, EtOAc:diethyl ether, to EtOAc, as eluent) afforded 358 as a yellow oil ( 0.041 g , $33 \%$ ): $R_{f .} 0.32$ (EtOAc, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 9.77$ (v br s, 1 H , $\mathrm{N} H), 6.61(\mathrm{dd}, J=12.8,7.4 \mathrm{~Hz}, 1 \mathrm{H}, H c), 5.84(\mathrm{ddt}, J=17.1,10.4,5.5 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{He})$,
5.21 (ddd, $\left.J=17.1,2.9,1.6 \mathrm{~Hz}, 1 \mathrm{H}, H f_{\text {cis }}\right), 5.16\left(10.4,2.9,1.6 \mathrm{~Hz}, 1 \mathrm{H}, H f_{\text {trans }}\right), 5.01$ (d, $J=7.4 \mathrm{~Hz}, 1 \mathrm{H}, H b), 3.78(\mathrm{ddt}, J=7.1,5.5,1.6 \mathrm{~Hz}, 2 \mathrm{H}, H d), 2.05(\mathrm{~s}, 3 \mathrm{H}, H a) \mathrm{ppm}$ (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta 9.77$ to disappear); ${ }^{13} \mathrm{C}$ NMR ( 126 MHz , $\mathrm{CDCl}_{3}$ ) $\delta 197.7$ (s, $C g$ ), 152.4 (d, Cc), 134.6 (d, Ce), 117.0 (t, Cf), 94.4 (d, Cb), 50.9 $(\mathrm{t}, C d), 29.1(\mathrm{~d}, C a)$; IR $v_{\text {max }}(t h i n ~ f i l m) ~ 3264,3056,1635(\mathrm{C}=\mathrm{O}), 1556,1487 \mathrm{~cm}^{-1}$; LRMS (TOF ES-), 153.1 (100\%), 124.2 (75\%) [M-H]; HRMS (TOF ES-), calculated for $\mathrm{C}_{7} \mathrm{H}_{10} \mathrm{NO}$, 124.0762; found 124.0759. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{249}$

Other procedure:
To allylamine ( $0.075 \mathrm{~mL}, 1 \mathrm{mmol}$ ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(0.5 \mathrm{~mL})$ was added 4-methoxy-3-buten-2-one ( $0.102 \mathrm{~mL}, 1 \mathrm{mmol}$ ). The reaction mixture was stirred at rt for 24 h and concentrated in vacuo to afford $\mathbf{3 5 8}$ as a brown oil ( $0.124 \mathrm{~g}, 99 \%$ ).

## $N$-Allyl-2,3-dihydro-2-phenyl-4-pyridone ${ }^{45}$

362

To 324 ( $0.146 \mathrm{~g}, 1 \mathrm{mmol}$ ) and $\mathrm{Yb}(\mathrm{OTf})_{3}(0.124 \mathrm{~g}, 0.2 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1.5 \mathrm{~mL})$ under argon was added Danishefsky's diene ( $0.240 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ) dropwise. The reaction mixture was stirred at rt overnight, quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(3 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$. The combined extracts were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (3:1, EtOAc:petroleum ether, as eluent) afforded $\mathbf{3 6 2}$ as an orange oil $(0.079 \mathrm{~g}, 37 \%)$ : $R_{f}$. 0.06 (1:1, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.41-7.30(\mathrm{~m}, 5 \mathrm{H}$, ArH), 7.19 (d, $J=7.7 \mathrm{~Hz}, 1 \mathrm{H}, H a), 5.78$ (dddd, $J=17.2,10.2,7.2,4.7 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Hi})$, 5.27 (ddd, $J=10.2,2.6,1.2 \mathrm{~Hz}, 1 \mathrm{H}, H_{j_{\text {trans }}}$, 5.18 (ddt, $J=17.2,1.7,1.2 \mathrm{~Hz}, 1 \mathrm{H}$, $\left.H j_{c i s}\right), 5.09(\mathrm{~d}, J=7.7 \mathrm{~Hz}, 1 \mathrm{H}, H b), 4.64\left(\mathrm{dd}, J=8.6,6.9 \mathrm{~Hz}, 1 \mathrm{H}, H d_{a x}\right), 3.73$ (ddt, $J=$ $15.5,4.7,1.7 \mathrm{~Hz}, 1 \mathrm{H}, H h), 3.59(\mathrm{ddt}, J=15.5,7.2,1.2 \mathrm{~Hz}, 1 \mathrm{H}, H h), 2.88(\mathrm{dd}, J=$ 16.4, $6.9 \mathrm{~Hz}, 1 \mathrm{H}, H c_{e q}$ ), $2.72\left(\mathrm{dd}, J=16.4,8.6 \mathrm{~Hz}, 1 \mathrm{H}, H c_{a x}\right) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( 101

## tert-Butyl 2-(3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)propyl)pyrrolidine-1carboxylate

468

To a stirred solution of $\mathbf{4 5 6}(0.223 \mathrm{~g}, 1.1 \mathrm{mmol})$ in dry THF $(0.5 \mathrm{~mL})$ under nitrogen at $0{ }^{\circ} \mathrm{C}$ was added $1 \mathrm{M} \mathrm{BH}_{3}$ solution in THF $(1.1 \mathrm{~mL}, 1.1 \mathrm{mmol})$. The reaction mixture was stirred at $0^{\circ} \mathrm{C}$ for 30 min , then at rt for 30 min before being quenched with methanol ( 0.5 mL ). Pinacol ( $0.201 \mathrm{~g}, 1.7 \mathrm{mmol}$ ) was added and the mixture was stirred at rt for 4 h and concentrated in vacuo. Purification by silica gel chromatography (8:2, hexane:diethyl ether, as eluent) afforded 468 as a colourless liquid ( $70 \mathrm{mg}, 20 \%$ ): $R_{f .} 0.54$ (1:1, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H}$ NMR ( 500 MHz , $\mathrm{CDCl}_{3}$ ) $\delta 3.74-3.59(\mathrm{~m}, 1 \mathrm{H}, H d), 3.38-3.18(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ha}), 1.89-1.67(\mathrm{~m}, 4 \mathrm{H}, \mathrm{Hc}+b)$, 1.66-1.55 (m, 2H, He), 1.41 (br s, 9H, Hi), 1.37-1.30 (m, 2H, Hf), 1.19 (br s, 12H, Hh), 0.79-0.68 (m, 2H, Hg ) ppm; ${ }^{13} \mathrm{C}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 227.4$ (s, Ck), 82.9 (s, Cj), 78.9 (s, Cl), 57.2 (d, Cd), 46.4 (46.0)(t, $C a), 37.6$ (36.9)(t, Ce), 30.7 (29.7)(t, $C c), 28.6(\mathrm{br} \mathrm{d}, C i), 24.9(24.9)(\mathrm{t}, C h), 23.1(\mathrm{t}, C b), 21.0(\mathrm{t}, C f), 11.4(\mathrm{t}, C g),{ }^{11} \mathrm{~B}$ NMR ( $128 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 34.0$; IR $v_{\text {max }}($ thin film) 297.5, 1691 (C=O), 1390 (BO) $\mathrm{cm}^{-1}$; LRMS (TOF ES+ $), 362.4$ (100\%) $[\mathrm{M}+\mathrm{Na}]^{+}, 340.4$ (45\%) $[\mathrm{M}+\mathrm{H}]^{+}, 284.3,240.3$; HRMS (TOF ES+ + , calculated for $\mathrm{C}_{18} \mathrm{H}_{34} \mathrm{BNO}_{4}+\mathrm{Na}^{+}, 361.2515$; found 361.2510 .

First alternate procedure:
To bis( 1,5 -cyclooctadiene)diiridium(I) dichloride $(0.020 \mathrm{~g}, 0.03 \mathrm{mmol})$ and $1,2-$ bis(diphenylphosphino)ethane ( $0.024 \mathrm{~g}, 0.06 \mathrm{mmol}$ ) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \mathrm{~mL})$ under nitrogen was added $456(0.422 \mathrm{~g}, 2 \mathrm{mmol})$ and pinacolborane ( $0.350 \mathrm{~mL}, 2.4 \mathrm{mmol}$ ). The resulting reaction mixture was left to stir at rt for 12 h before being quenched with methanol $(2 \mathrm{~mL})$ and water $(6 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by
silica gel chromatography (5\%-20\%, EtOAc:hexane, as eluent) afforded 468 as a colourless oil ( $0.551 \mathrm{~g}, 81 \%$ ).

Second alternate procedure:
To tris(triphenylphosphine)rhodium(I)chloride ( $0.009 \mathrm{~g}, 0.01 \mathrm{mmol}$ ) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ under nitrogen was added $456(0.211 \mathrm{~g}, 1 \mathrm{mmol})$ and pinacolborane $(0.175 \mathrm{~mL}$, $1.2 \mathrm{mmol})$. The resulting reaction mixture was left to stir at rt for 60 h before being quenched with methanol $(1 \mathrm{~mL})$ and water $(3 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times$ $5 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (5\%-20\%, EtOAc:hexane, as eluent) afforded 468 as a colourless oil $(0.184 \mathrm{~g}, 54 \%)$.

## (3-(Pyrrolidin-2-yl)propyl)boronic acid hydrochloride

473

To $468(0.260 \mathrm{~g}, 0.77 \mathrm{mmol})$ was added $20 \%$ ( aq ) $\mathrm{HCl}(1 \mathrm{~mL})$ and the reaction mixture was stirred at $80^{\circ} \mathrm{C}$. After 2 h , the mixture was cooled to rt , diluted with water ( 5 mL ), washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$ and the aqueous concentrated in vacuo, with azeotroping with toluene ( $3 \times 5 \mathrm{~mL}$ ), to afford 473 as a colourless thick oil ( $0.147 \mathrm{~g}, 99 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( $700 \mathrm{MHz}, \mathrm{D}_{2} \mathrm{O}$ ) $\delta 3.35(\mathrm{dq}, J=9.2,7.3 \mathrm{~Hz}, 1 \mathrm{H}, H d$ ), 3.14-3.06 (m, 2H, Ha), 2.01 (dtd, $J=13.1,7.3,4.0 \mathrm{~Hz}, 1 \mathrm{H}, H c$ ), 1.88-1.83 (m, 1H, $H c), 1.82-1.75(\mathrm{~m}, 1 \mathrm{H}, H b), 1.57-1.51(\mathrm{~m}, 1 \mathrm{H}, \mathrm{He}), 1.51-1.46(\mathrm{~m}, 1 \mathrm{H}, \mathrm{He}), 1.46-1.41$ (m, 1H, Hb), 1.28 (quin, $J=8.0 \mathrm{~Hz}, 2 \mathrm{H}, H f), 0.63(\mathrm{t}, J=8.0 \mathrm{~Hz}, 2 \mathrm{H}, H g) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $\left.176 \mathrm{MHz}, \mathrm{D}_{2} \mathrm{O}\right) \delta 60.5$ (60.6) (d, Cd), $45.0(\mathrm{t}, C a), 34.1(\mathrm{t}, C e), 29.6(\mathrm{t}, C c)$, $23.0(\mathrm{t}, C b), 20.9(\mathrm{t}, C f), 13.9(\mathrm{t}, C g) ;{ }^{11} \mathrm{~B}$ NMR ( $128 \mathrm{MHz}, \mathrm{D}_{2} \mathrm{O}$ ) $\delta 32.6$; IR $v_{\max }$ (neat) 3350 (br, OH), $2934(\mathrm{CH})$, and $1370(\mathrm{BO}) \mathrm{cm}^{-1}$; LRMS (ES+) 186.17 (100\%), 172.15 (95\%), 158.13 (35\%) $[\mathrm{M}+\mathrm{H}]^{+}, 154.14$ (25\%), 140.12 (8\%); HRMS (ES+), calculated for $\mathrm{C}_{7} \mathrm{H}_{16} \mathrm{O}_{2} \mathrm{~N}^{10} \mathrm{~B}+\mathrm{H}^{+}, 157.1383$; found 157.1381.

## ( $\boldsymbol{R}$ )-tert-Butoxycarbonyl 2-propenyl-pyrrolidine ${ }^{270}$

475

To (-)-sparteine ( $0.28 \mathrm{~g}, 1.2 \mathrm{mmol}$ ) in dry ether ( 4.8 mL ) under argon at $-78^{\circ} \mathrm{C}$ was added dropwise sec-BuLi ( $2 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ). After $30 \mathrm{~min}, 455(0.174 \mathrm{~mL}, 1 \mathrm{mmol})$ was added to the reaction mixture. After 6 h , a solution of $\mathrm{ZnCl}_{2}(0.177 \mathrm{~g}, 1.3 \mathrm{mmol})$ in dry THF ( 1.7 mL ) was added to the reaction mixture dropwise over 10 min . After 30 min , a solution of $\mathrm{CuCN}(0.107 \mathrm{~g}, 1.2 \mathrm{mmol})$ and $\mathrm{LiCl}(0.102 \mathrm{~g}, 2.4 \mathrm{mmol})$ in dry THF ( 6 mL ) was added rapidly to the reaction mixture. After a further 30 min , allyl bromide $(0.261 \mathrm{~mL}, 3 \mathrm{mmol})$ was added to the reaction mixture dropwise and was allowed to warm to rt overnight. The reaction mixture was quenched with saturated (aq) $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ and diluted with diethyl ether $(10 \mathrm{~mL})$. After stirring for 5 min , the mixture was filtered, extracted with diethyl ether $(3 \times 10 \mathrm{~mL})$ and the combined organics dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography ( $9: 1$, hexane:diethyl ether, as eluent) afforded 475 as a colourless oil $(0.203 \mathrm{~g}, 96 \%, 82 \% \mathrm{ee}):[\alpha]_{\mathrm{D}}{ }^{22}{ }^{\circ} \mathrm{C}=+40.98\left(\mathrm{c}=1.00, \mathrm{CHCl}_{3}\right)$; The enantiomeric ratio of the product was determined by chiral HPLC using OJ-Chiralsel column ( $250 \times 4.6$ mm ), $25^{\circ} \mathrm{C}, 0.5 \mathrm{~mL} / \mathrm{min}, 210 \mathrm{~nm}$, hexane:IPA (99.8:0.2), $t_{\mathrm{R}}(R)=11.1 \mathrm{~min} ; t_{\mathrm{R}}(S)=$ 12.5 min . All other spectroscopic and analytical properties were identical to the racemic compound 456.

First alternate procedure:
To (-)-sparteine ( $0.28 \mathrm{~g}, 1.2 \mathrm{mmol}$ ) in dry ether ( 4.8 mL ) under argon at $-78{ }^{\circ} \mathrm{C}$ was added dropwise sec-BuLi ( $2 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ). After $30 \mathrm{~min}, 455$ ( $0.174 \mathrm{~mL}, 1 \mathrm{mmol}$ ) was added to the reaction mixture. After 1 h , a solution of $\mathrm{ZnCl}_{2}(0.177 \mathrm{~g}, 1.3 \mathrm{mmol})$ in dry THF ( 1.7 mL ) was added to the reaction mixture dropwise over 10 min . After 30 min , a solution of $\mathrm{CuCN}(0.107 \mathrm{~g}, 1.2 \mathrm{mmol})$ and $\mathrm{LiCl}(0.102 \mathrm{~g}, 2.4 \mathrm{mmol})$ in dry THF ( 6 mL ) was added rapidly to the reaction mixture. After a further 30 min , allyl
bromide ( $0.261 \mathrm{~mL}, 3 \mathrm{mmol}$ ) was added to the reaction mixture dropwise and was allowed to warm to rt overnight. The reaction mixture was quenched with saturated (aq) $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ and diluted with diethyl ether $(10 \mathrm{~mL})$. After stirring for 5 min , the mixture was filtered, extracted with diethyl ether $(3 \times 10 \mathrm{~mL})$ and the combined organics dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (9:1, hexane:diethyl ether, as eluent) afforded 475 as a colourless oil ( $0.169 \mathrm{~g}, 80 \%, 82 \% \mathrm{ee}$ );

Second alternate procedure:
To a stirred solution of $455(0.174 \mathrm{~mL}, 1.0 \mathrm{mmol})$ and (-)-sparteine $(0.28 \mathrm{~g}$, $1.2 \mathrm{mmol})$ in dry diethyl ether ( 4 mL ) under nitrogen at $-78^{\circ} \mathrm{C}$ was added dropwise sec-BuLi ( $1.3 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ). After 1 h , a solution of $\mathrm{CuCN}(0.045 \mathrm{~g}, 0.5 \mathrm{mmol})$ and $\mathrm{LiCl}(0.043 \mathrm{~g}, 1.0 \mathrm{mmol})$ in dry THF $(3 \mathrm{~mL})$ was added rapidly to the reaction mixture. After a further hour, allyl bromide $(0.0 .86 \mathrm{~mL}, 1 \mathrm{mmol})$ was added and the reaction mixture was allowed to warm to rt overnight. The reaction mixture was quenched with saturated (aq) $\mathrm{NH}_{4} \mathrm{Cl}(5 \mathrm{~mL})$ and diluted with diethyl ether ( 5 mL ). After stirring for 5 min , the mixture was filtered, extracted with diethyl ether ( $3 \times$ 5 mL ) and the combined organics dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (9:1, hexane:diethyl ether, as eluent) afforded 475 as a colourless oil ( $0.133 \mathrm{~g}, 63 \%, 69 \%$ ee);

Third alternate procedure:
To a stirred solution of $\mathbf{4 5 5}(0.174 \mathrm{~mL}, 1.0 \mathrm{mmol})$ and (-)-sparteine ( 0.28 g , $1.2 \mathrm{mmol})$ in dry diethyl ether ( 4 mL ) under nitrogen at $-78{ }^{\circ} \mathrm{C}$ was added dropwise sec-BuLi ( $1.3 \mathrm{~mL}, 1.2 \mathrm{mmol}$ ). ). After 1 h , allyl bromide ( $0.043 \mathrm{~mL}, 0.5 \mathrm{mmol}$ ) was added and the reaction mixture was allowed to warm to rt overnight. The reaction mixture was quenched with saturated (aq) $\mathrm{NH}_{4} \mathrm{Cl}(5 \mathrm{~mL})$ and diluted with diethyl ether ( 5 mL ). After stirring for 5 min , the mixture was filtered, extracted with diethyl ether $(3 \times 5 \mathrm{~mL})$ and the combined organics dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography ( $9: 1$, hexane:diethyl ether, as eluent) afforded 475 as a colourless oil ( $0.068 \mathrm{~g}, 64 \%, 19 \%$ ee $)$.

## (S)-tert-Butyl 2-(3-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-

 yl)propyl)pyrrolidine-1-carboxylate

476

To bis( 1,5 -cyclooctadiene)diiridium(I) dichloride $(0.020 \mathrm{~g}, 0.03 \mathrm{mmol})$ and $1,2-$ bis(diphenylphosphino)ethane ( $0.024 \mathrm{~g}, 0.06 \mathrm{mmol}$ ) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \mathrm{~mL})$ under nitrogen was added $475(0.422 \mathrm{~g}, 2 \mathrm{mmol})$ and pinacolborane ( $0.350 \mathrm{~mL}, 2.4 \mathrm{mmol}$ ). The resulting reaction mixture was left to stir at rt for 12 h before being quenched with methanol $(2 \mathrm{~mL})$ and water $(6 \mathrm{~mL})$ and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography ( $5 \%-20 \%$, EtOAc:hexane, as eluent) afforded 476 as a colourless oil $(0.551 \mathrm{~g}, 81 \%):[\alpha]_{\mathrm{D}}{ }^{22}{ }^{\circ} \mathrm{C}=33.94$ at $\mathrm{c}=1$. All other spectroscopic and analytical properties were identical to the racemic compound 468.

## (S)-(3-(Pyrrolidin-2-yl)propyl)boronic acid hydrochloride

477

To $476(0.260 \mathrm{~g}, 0.77 \mathrm{mmol})$ was added $20 \%$ (aq) $\mathrm{HCl}(1 \mathrm{~mL})$ and the reaction mixture was stirred at $80^{\circ} \mathrm{C}$. After 2 h , the mixture was cooled to rt , diluted with water ( 5 mL ), washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$ and the aqueous concentrated in vacuo, with azeotroping with toluene ( $3 \times 5 \mathrm{~mL}$ ), to afford 477 as a colourless thick oil ( $0.147 \mathrm{~g}, 99 \%$ ): All spectroscopic and analytical properties were identical to the racemic compound 473.

## (S)-(3-(Pyrrolidin-2-yl)propyl)boronic acid

478

To $477(0.034 \mathrm{~g}, 0.1 \mathrm{mmol})$ was added $20 \%(\mathrm{aq}) \mathrm{HCl}(2 \mathrm{~mL})$ and the reaction mixture was stirred at $80{ }^{\circ} \mathrm{C}$ for 2 h . The reaction mixture was subsequently washed with EtOAc $(3 \times 5 \mathrm{~mL})$ and the aqueous reaction mixture was concentrated in vacuo and azeotroped with toluene $(3 \times 5 \mathrm{~mL})$. The reaction mixture was diluted in $\mathrm{CDCl}_{3}$ $(1 \mathrm{~mL})$, to which was added triethylamine $(0.014 \mathrm{~mL}, 0.1 \mathrm{mmol})$ and the mixture was stirred under argon overnight to afford a solution containing 478: ${ }^{11} \mathrm{~B}$ NMR $=5 \mathrm{ppm}$.

## 2-(Chloromethyl)-4,4,5,5-tetramethyl-1,3,2-dioxaborolane ${ }^{271}$

486

To a stirred solution of bromochloromethane ( $2.00 \mathrm{~mL}, 31 \mathrm{mmol}$ ) and triisopropyl borate ( $6.46 \mathrm{~mL}, 28 \mathrm{mmol}$ ) in dry THF ( 28 mL ) under argon was added dropwise $n-\operatorname{BuLi}(15 \mathrm{~mL}, 34 \mathrm{mmol})$ at $-78^{\circ} \mathrm{C}$ and the reaction mixture was stirred for 1 h prior to allowing to warm to rt overnight. The reaction mixture was subsequently quenched with $20 \%(\mathrm{aq}) \mathrm{HCl}(6 \mathrm{~mL})$ and extracted with diethyl ether ( $3 \times 10 \mathrm{~mL}$ ). The combined organics were washed with brine $(10 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford a crude white solid ( 0.843 g ). This was dissolved in diethyl ether $(10 \mathrm{~mL})$ prior to adding 0.85 Equivalents of pinacol $(0.93 \mathrm{~g}, 7.9 \mathrm{mmol})$. The reaction mixture was left to stir at rt overnight and then concentrated in vacuo. Purification by distillation under vacuum ( $32 \mathrm{mbar}, 9{ }^{\circ} \mathrm{C}$ ) afforded 486 as a colourless oil ( 1.01 g , $20 \%$ ): $R_{f} .0 .34$ (3:1, hexane:diethyl ether, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ $2.97(\mathrm{~s}, 2 \mathrm{H}, H a), 1.30(\mathrm{~s}, 12 \mathrm{H}, \mathrm{Hb}) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 84.6(\mathrm{~d}, \mathrm{Ca})$, $82.8(\mathrm{~s}, \mathrm{Cb}), 24.8(\mathrm{~d}, C c) ;{ }^{11} \mathrm{~B} \operatorname{NMR}\left(128 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 31.5$; IR $v_{\text {max }}$ (neat) 2979,

1372, $1348 \mathrm{~cm}^{-1}$. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{272}$
(S)-tert-Butyl 2-((4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)methyl)pyrrolidine-1-carboxylate ${ }^{161}$

487

To (-)-sparteine ( $0.87 \mathrm{~mL}, 3.8 \mathrm{mmol}$ ) in dry diethyl ether ( 20 mL ) under argon at $-78{ }^{\circ} \mathrm{C}$ was added dropwise sec-BuLi ( $3 \mathrm{~mL}, 3.8 \mathrm{mmol}$ ). After stirring for 20 min , $N$-Boc pyrrolidine ( $0.522 \mathrm{~mL}, 3 \mathrm{mmol}$ ) was added dropwise to the reaction mixture and stirred for 2 h prior to the dropwise addition of 486 ( $0.62 \mathrm{~g}, 3.5 \mathrm{mmol})$. After $30 \mathrm{~min}, \mathrm{ZnCl}_{2}$ ( 1 M in diethyl ether) $(5.6 \mathrm{~mL}, 5.6 \mathrm{mmol})$ was added to the reaction mixture and stirred for 45 min before being allowed to warm to rt overnight. The suspension was quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(10 \mathrm{~mL})$, filtered through Celite and washed with $5 \%(\mathrm{aq}) \mathrm{HCl}(5 \mathrm{~mL})$. The phases were separated and the aqueous phase extracted with diethyl ether $(2 \times 8 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford a crude oil. Purification by silica gel chromatography (5:1, hexane:diethyl ether, as eluent) afforded 487 as a colourless oil ( $0.391 \mathrm{~g}, 42 \%, 96 \%$ ): $R_{f .} 0.18$ (3:1, hexane:diethyl ether, as eluent); $[\alpha]_{\mathrm{D}}{ }^{22}{ }^{\circ} \mathrm{C}=+33.2$ (c $\left.=1.00, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right) ;{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 3.99-3.90(\mathrm{br} \mathrm{m}, 1 \mathrm{H}, \mathrm{Hd})$, 3.383.30 (br d, 2H, Ha), 2.02 (br s, 1H, Hc), 1.87-1.81 (m, 1H, Hb), 1.70-1.75 (m, 1H, $H b), 1.15(\mathrm{br} \mathrm{s}, 1 \mathrm{H}, H c), 1.45(\mathrm{~s}, 9 \mathrm{H}, H g), 1.23(\mathrm{~s}, 12 \mathrm{H}, H f), 0.84-1.00(\mathrm{~m}, 2 \mathrm{H}, \mathrm{He})$ ppm; ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 154.7$ ( $\left.\mathrm{s}, C i\right), 83.1$ (s, Ch), 79.0 ( $\mathrm{s}, C j$ ), 54.3 (d, $C d), 46.6$ and 46.3 (t, $C a$ ), 33.4 and 33.1 (t, $C c$ ), 28.7 (d, $C g$ ), 25.1 and 24.9 (d, $C f$ ), 23.9 and $23.4(\mathrm{t}, \mathrm{Cb}), 18.5(\mathrm{t}, \mathrm{Ce}) ;{ }^{11} \mathrm{~B}$ NMR ( $128 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 32.8$; IR $v_{\text {max }}$ (thin film) $2972(\mathrm{CH}), 1693(\mathrm{C}=\mathrm{O}), 1389$ and $1366(\mathrm{BO}) \mathrm{cm}^{-1}$; LRMS (TOF ES+), 334.3 (100\%) $[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{16} \mathrm{H}_{30} \mathrm{BNO}_{4}+\mathrm{Na}^{+}$, 334.2202;
found 334.2209 . The enantiomeric ratio of the product was determined by GC using CP-Chiralsil-Dex-CB column ( $35 \mathrm{~m} \times 0.25 \mathrm{~mm} \times 0.25 \mu \mathrm{~m}$ ), $128^{\circ} \mathrm{C}, \operatorname{FID}, t_{\mathrm{R}}(S)=124$ $\min ; t_{\mathrm{R}}(R)=127 \mathrm{~min}$. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{161}$

## (S)-(Pyrrolidin-2-ylmethyl)boronic acid hydrochloride ${ }^{161}$

488

To $487(0.300 \mathrm{~g}, 0.96 \mathrm{mmol})$ was added $20 \%$ ( aq$) \mathrm{HCl}(1 \mathrm{~mL})$ and the reaction mixture was stirred at $80^{\circ} \mathrm{C}$. After 2 h , the mixture was cooled to rt , diluted with water ( 5 mL ), washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$ and the aqueous concentrated in vacuo, with azeotroping with toluene ( $3 \times 5 \mathrm{~mL}$ ), to afford $\mathbf{4 8 8}$ as an off-colourless oil $(0.155 \mathrm{~g}, 98 \%): \quad[\alpha]_{\mathrm{D}}{ }^{22}{ }^{\circ} \mathrm{C}=+33.0\left(\mathrm{c}=1.00, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right) ;{ }^{1} \mathrm{H}$ NMR $(400 \mathrm{MHz}$, $\mathrm{CDCl}_{3}$ ) $\delta$ 3.77-3.73 (m, 1H, Hd), 3.37-3.29 (m, 2H, Ha), 2.29-2.25 (m, 1H, Hc), 2.12$2.00(\mathrm{~m}, 1 \mathrm{H}, H b), 1.68-1.64(\mathrm{~m}, 1 \mathrm{H}, H c), 1.39(\mathrm{dd}, J=15.4,7 \mathrm{~Hz}, 1 \mathrm{H}, H e), 1.27(\mathrm{dd}$, $j=15.4,9.1 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{He}) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 18.2(\mathrm{t}, \mathrm{Ce}), 23.1(\mathrm{t}$, $C b), 31.5(\mathrm{t}, C c), 44.8(\mathrm{t}, C a), 58.2(\mathrm{~d}, C d) ;{ }^{11} \mathrm{~B} \operatorname{NMR}\left(128 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 31.0$; IR $v_{\max }$ (thin film) $2980(\mathrm{CH})$ and $1365(\mathrm{BO}) \mathrm{cm}^{-1}$. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{161}$

## $N$-tert-Butoxycarbonyl-L-proline ${ }^{273}$

489

To L-proline ( $1.50 \mathrm{~g}, 13.0 \mathrm{mmol}$ ) at $0{ }^{\circ} \mathrm{C}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(30 \mathrm{~mL})$ was added triethylamine ( $2.36 \mathrm{~mL}, 16.9 \mathrm{mmol}$ ), followed by di-tert-butyl-dicarbonate ( $3.98 \mathrm{~g}, 18.2 \mathrm{mmol}$ ). The reaction mixture was stirred at rt for 2.5 h , quenched with sat. (aq) citric acid $(8 \mathrm{~mL})$ and washed with brine $(2 \times 10 \mathrm{~mL})$ and water $(10 \mathrm{~mL})$. The organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. The crude solid was dissolved in hot EtOAc, followed by the addition of hexane ( 40 mL ). The mixture was crystallised and filtered to afford 489 as a white solid ( $2.19 \mathrm{~g}, 78 \%$ ): m.p. 134-135 ${ }^{\circ} \mathrm{C}$ (lit. 134-135 $\left.{ }^{\circ} \mathrm{C}\right)^{274} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 10.9$ (br s, $1 \mathrm{H}, \mathrm{OH}$ ), 4.36-4.18 (m, $1 \mathrm{H}, \mathrm{Hd}$ ), 3.58-3.31 (m, 2H, Ha), 2.31-2.17 (m, 1H, Hc), 2.15-1.98 (m, 1H, Hb), 1.98-1.80 (m, $2 \mathrm{H}, H b+c), 1.40+1.46(2 \mathrm{x} \mathrm{s}, 9 \mathrm{H}, H \mathrm{~h}) \mathrm{ppm}$ (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta$ 10.9 to disappear); ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 178.8$ (175.7) ( $\mathrm{s}, C f$ ), 156.2 (154.1) (s, $C g$ ), 81.3 (80.5) (s, Ch), 59.1 (d, Cd), 47.0 (46.5) (t, $C a$ ), 31.0 (29.0) (t, Cc), 28.5 (28.4) (d, Ce), 24.4 (23.8) (t, Cb); IR $v_{\max }$ (neat) $2969(\mathrm{OH}), 1736(\mathrm{C}=\mathrm{O}), 1632$ $(\mathrm{NC}=\mathrm{O}) \mathrm{cm}^{-1}$; LRMS (TOF ES+) 238.6 ( $100 \%$ ) $[\mathrm{M}+\mathrm{Na}]^{+}, 160.4$ (40\%), 114.4 ( $80 \%$ ), 116.4 (95\%); HRMS (TOF ES+), calculated for $\mathrm{C}_{10} \mathrm{H}_{17} \mathrm{NO}_{4}+\mathrm{Na}^{+}, 238.1055$; found 238.1058. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{275}$

## (S)-tert-Butyl 2-(hydroxymethyl)pyrrolidine-1-carboxylate ${ }^{276}$

490

To $489(0.60 \mathrm{~g}, 2.79 \mathrm{mmol})$ in dry THF $(5 \mathrm{~mL})$ under argon at rt was added dropwise $\mathrm{BH}_{3} \cdot \mathrm{DMS}(0.306 \mathrm{~mL}, 3.06 \mathrm{mmol})$ and refluxed for 2 h . The reaction mixture was cooled to rt , after which was added ice ( 2.5 g ) and the mixture extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(3 \times 15 \mathrm{~mL})$. The combined organics were filtered through Celite and the filtrate concentrated in vacuo to afford a crude solid. This was washed with cold diethyl ether to afford 490 as a white solid ( $0.394 \mathrm{~g}, 70 \%$ ): m.p. $54-55{ }^{\circ} \mathrm{C}$ (lit. $55-56{ }^{\circ} \mathrm{C}$ ) $)^{277} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 4.74$ (br s, $1 \mathrm{H}, \mathrm{OH}$ ), 3.95 (br s, $1 \mathrm{H}, H d$ ), 3.64-3.56 (m,

2H, Ha), 3.46-3.43 (m, 1H, He), 3.32-3.29 (m, 1H, He), 2.03-1.98 (m, 1H, Hc), 1.86$1.74(\mathrm{~m}, 2 \mathrm{H}, H b), 1.59-1.56(\mathrm{~m}, 1 \mathrm{H}, H c), 1.47(\mathrm{br} \mathrm{s}, 9 \mathrm{H}, H f) \mathrm{ppm}$ (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta 4.74$ to disappear); ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 157.2$ (s, Cg), 80.2 ( $\mathrm{s}, C h$ ), 67.7 (t, Ce), 60.2 (d, Cd), 47.5 (t, Ca), 28.7 (t, Cc), 28.5 (d, Cf), $24.1(\mathrm{t}, \mathrm{Cb})$; IR $v_{\max }$ (neat) $3426(\mathrm{OH}), 2980(\mathrm{CH}), 1652(\mathrm{C}=\mathrm{O}), 1403 \mathrm{~cm}^{-1}$; LRMS (TOF ES+), 224.3 (100\%) [M+Na] ${ }^{+}, 146.2$ ( $80 \%$ ), 102.2 (70\%); HRMS (TOF ES+), calculated for $\mathrm{C}_{10} \mathrm{H}_{19} \mathrm{NO}_{3}+\mathrm{Na}^{+}$, 224.1263; found 224.1270. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{277,278}$

## (S)-tert-Butyl 2-(iodomethyl)pyrrolidine-1-carboxylate ${ }^{279}$

491

To imidazole ( $0.20 \mathrm{~g}, 2.98 \mathrm{mmol}$ ) and triphenylphosphine ( $0.59 \mathrm{~g}, 2.24 \mathrm{mmol}$ ) in diethyl ether $(4 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$ under argon was added portionwise iodine $(0.57 \mathrm{~g}$, $2.24 \mathrm{mmol})$. The reaction mixture was stirred for 10 min prior to addition of a solution of $\mathbf{4 9 0}(0.30 \mathrm{~g}, 1.49 \mathrm{~mol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(2 \mathrm{~mL})$. The mixture was stirred at rt for 5 h , filtered and concentrated in vacuo. Purification by silica gel chromatography (9:1-3:1, hexane:diethyl ether, as eluent) afforded 491 as a white solid ( $0.287 \mathrm{~g}, 62 \%$ ): m.p. $37-38{ }^{\circ} \mathrm{C}\left(\text { lit. } 38-40{ }^{\circ} \mathrm{C}\right)^{280} ;{ }^{1} \mathrm{H} \operatorname{NMR}\left(700 \mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 3.90-3.80(\mathrm{~m}, 1 \mathrm{H}$, $H d)$, 3.50-3.11 (m, 4H, Ha+He), 2.08-2.01 (m, 1H, Hc), 1.93-1.75 (m. 3H, Hb+Hc), $1.46+1.44(2 \mathrm{x} \mathrm{s}, 9 \mathrm{H}, \mathrm{Hf}) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $176 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 154.5$ (154.2) ( $\mathrm{s}, \mathrm{Cg}$ ), 80.0 (79.7) (s, Ch), 58.2 (58.0) (t, Cd), 47.6 (47.2) (d, Ca), 31.7 (31.2) (d, Cc), 28.6 (t, $C f$ ), 23.6 (22.9) (d, Cb), 11.1 (10.8) (d, Ce); IR $v_{\text {max }}$ (neat) 2974 (CH), 1687 (C=O) $\mathrm{cm}^{-1}$; LRMS (TOF ES+) 242.7 (100\%), 234.5 (90\%) [M+Na] ${ }^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{10} \mathrm{H}_{18} \mathrm{NO}_{2}+\mathrm{Na}^{+}, 334.0280$; found 334.0296. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{202}$

## (R)-tert-Butyl 2-((4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-

 yl)methyl)pyrrolidine-1-carboxylate ${ }^{202}$

492

To $491(0.50 \mathrm{~g}, 1.6 \mathrm{mmol})$ in dry THF ( 4 mL ) under argon was added $\mathrm{B}_{2} \mathrm{pin}_{2}(0.41 \mathrm{~g}$, $1.6 \mathrm{mmol}), \mathrm{LiO}^{\mathrm{t}} \mathrm{Bu}(0.26 \mathrm{~g}, 3.2 \mathrm{mmol})$ and $\mathrm{CuI}(0.175 \mathrm{~g}, 3.2 \mathrm{mmol})$. The reaction mixture was stirred at rt for 20 h , quenched with $5 \%(\mathrm{aq}) \mathrm{HCl}(5 \mathrm{~mL})$, extracted with diethyl ether $(3 \times 5 \mathrm{~mL})$ and the combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (4:1, hexane:EtOAc, as eluent) afforded 492 as a colourless oil $\left(0.170 \mathrm{~g}, 34 \%, 97 \%\right.$ ee): $[\alpha]_{\mathrm{D}}{ }^{22}{ }^{\circ} \mathrm{C}=-36.4$ (c $=1.00, \mathrm{CH}_{2} \mathrm{Cl}_{2}$ ); The enantiomeric ratio of the product was determined by GC using CP-Chiralsil-Dex-CB column ( $35 \mathrm{~m} \times 0.25 \mathrm{~mm} \times 0.25 \mu \mathrm{~m}$ ), $128^{\circ} \mathrm{C}, \mathrm{FID}, t_{\mathrm{R}}(S)=124$ $\min ; t_{\mathrm{R}}(R)=127 \mathrm{~min}$. All other spectroscopic and analytical properties were identical to the opposite enantiomer 487.

## (S)-(Pyrrolidin-2-ylmethyl)boronic acid hydrochloride ${ }^{202}$

493

To $492(0.300 \mathrm{~g}, 0.96 \mathrm{mmol})$ was added $20 \%$ (aq) $\mathrm{HCl}(1 \mathrm{~mL})$ and the reaction mixture was stirred at $80^{\circ} \mathrm{C}$. After 2 h , the mixture was cooled to rt , diluted with water ( 5 mL ), washed with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 5 \mathrm{~mL})$ and the aqueous concentrated in vacuo, with azeotroping with toluene ( $3 \times 5 \mathrm{~mL}$ ), to afford 493 as an off-colourless
oil ( $0.152 \mathrm{~g}, 96 \%):[\alpha]_{\mathrm{D}}{ }^{22}{ }^{\circ} \mathrm{C}=-33.2\left(\mathrm{c}=1.00, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$. All other spectroscopic and analytical properties were identical to the opposite enantiomer 488.

## 2-Phenyl-1-(phenylsulfonyl)-2,3-dihydropyridin-4(1H)-one ${ }^{281}$

496

To $N$-benzylidenebenzenesulonamide ( $0.491 \mathrm{~g}, 2 \mathrm{mmol}$ ) in toluene ( 2 mL ) was added Danishefsky's diene $4(0.5 \mathrm{~mL}, 2.5 \mathrm{mmol})$ and the reaction mixture was stirred at $100{ }^{\circ} \mathrm{C}$ under nitrogen. After 4 h the mixture was cooled to rt and concentrated in vacuo. Purification by silica gel chromatography ( $5 \%-35 \%$, EtOAc:hexane, as eluent) afforded 496 as a yellow oil ( $0.389 \mathrm{~g}, 62 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.83$ (dd, $J=8.3,1.5 \mathrm{~Hz}, 1 \mathrm{H}, H a), 7.72-7.69(\mathrm{~m}, 2 \mathrm{H}, H h), 7.59-7.55(\mathrm{~m}, 1 \mathrm{H}, H j), 7.46-7.55(\mathrm{~m}$, $1 \mathrm{H}, H j$ ), 7.20-7.12 (m, 5H, He+f+g), $5.55(\mathrm{dt}, J=7.2,1.5 \mathrm{~Hz}, 1 \mathrm{H}, H d), 5.43(\mathrm{dd}, J=$ $8.3,1.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Hb}), 2.87\left(\mathrm{dd}, J=16.5,7.2 \mathrm{~Hz}, 1 \mathrm{H}, H c_{\text {trans }}\right), 2.68(J=16.5,1.5,1.2$ $\left.\mathrm{Hz}, 1 \mathrm{H}, H c_{c i s}\right) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 190.5$ (s, Ck), 142.5 (d, Ca), 138.7 (s, Cl), 137.0 (s, Cm), 133.9 (d, Cj), 129.6 (d, Ci), 128.9 (d, Cf), 128.3 (d, $C g$ ), 127.1 (d, Ch), 126.4 (d, $C e$ ), 108.6 (d, $C b$ ), 57.9 (d, $C d$ ), 42.0 (t, Cc); LRMS (TOF ES+), 336.2 ( $100 \%$ ) $[\mathrm{M}+\mathrm{Na}]^{+}, 314.2$ (45\%) $[\mathrm{M}+\mathrm{H}]^{+}, 242.2$ (45\%); HRMS (TOF ES+), calculated for $\mathrm{C}_{17} \mathrm{H}_{15} \mathrm{NO}_{3} \mathrm{~S}+\mathrm{H}^{+}$, 314.0851; observed 314.0836. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{282}$

## 4-Hydroxy-4-(4-nitrophenyl)butan-2-one ${ }^{245}$

505

To $473(0.039 \mathrm{~g}, 0.2 \mathrm{mmol})$ and triethylamine $(0.028 \mathrm{~mL}, 0.2 \mathrm{mmol})$ in acetone $(1 \mathrm{~mL})$ was added $p$-nitrobenzaldehyde $(0.151 \mathrm{~g}, 1 \mathrm{mmol})$ and the reaction mixture was left to stir at rt. After 72 h , the mixture was quenched with sat. (aq) $\mathrm{NH}_{4} \mathrm{Cl}$ $(10 \mathrm{~mL})$, extracted with EtOAc $(15 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (1:4-1:0, EtOAc:hexane, as eluent) afforded 507 as an orange solid ( $0.008 \mathrm{~g}, 4 \%$ ), $\mathbf{5 0 6}$ as an off-colourless solid ( $0.126 \mathrm{~g}, 69 \%$ ), and 505 as an off-colourless solid $\left(0.056 \mathrm{~g}, 27 \%, 0 \%\right.$ ee): $R_{f .} 0.19$ (1:1, EtOAc:hexane, as eluent); m.p. $57-59{ }^{\circ} \mathrm{C}$ (lit. $58-60{ }^{\circ} \mathrm{C}$ ) ${ }^{283}$; ${ }^{1} \mathrm{H}$ NMR ( 400 MHz , $\mathrm{CDCl}_{3}$ ) $\delta 8.14-8.09(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ha}), 7.51-7.47(\mathrm{~m}, 2 \mathrm{H}, H b), 5.22(\mathrm{t}, J=6.2 \mathrm{~Hz}, 1 \mathrm{H}, H c)$, 3.56 (br s, 1H, OH), $2.83(\mathrm{~d}, J=6.2 \mathrm{~Hz}, 2 \mathrm{H}, H d), 2.18(\mathrm{~s}, 3 \mathrm{H}, \mathrm{He})$ ppm (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta 3.56$ to disappear); ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 208.5$ (s, Ch), 150.3 ( s, Cf), 147.2 ( s, $C g$ ), 126.5 (d, $C a$ ), 123.7 (d, Cb), 68.8 (d, $C c$ ), 51.6 (t, $C d), 30.7(\mathrm{~d}, \mathrm{Ce})$; IR $v_{\text {max }}$ (thin film) $3431(\mathrm{OH}), 1710(\mathrm{C}=\mathrm{O}), 1514(\mathrm{Ar}), 1343\left(\mathrm{NO}_{2}\right)$ $\mathrm{cm}^{-1}$; LRMS (TOF ES-), 208.1 ( $95 \%$ ) [M-H] ${ }^{-}$, 190.1 (100\%); HRMS (TOF ES-), calculated for $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{NO}_{4}, 208.0610$; found 208.0585. The enantiomeric ratio of the product was determined by chiral HPLC using OJ-H-Chiralsel column ( $250 \times 4.6$ $\mathrm{mm}), 15^{\circ} \mathrm{C}, 1 \mathrm{~mL} / \mathrm{min}, 210 \mathrm{~nm}$, hexane:IPA (9:1), $t_{\mathrm{R}}(S)=39.7 \mathrm{~min} ; t_{\mathrm{R}}(R)=45.9 \mathrm{~min}$. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{202}$

## 1,5-Dihydroxy-1,5-bis(4-nitrophenyl)pentan-3-one ${ }^{284}$

506

To $473(0.039 \mathrm{~g}, 0.2 \mathrm{mmol})$ and triethylamine $(0.028 \mathrm{~mL}, 0.2 \mathrm{mmol})$ in acetone $(1 \mathrm{~mL})$ was added $p$-nitrobenzaldehyde $(0.151 \mathrm{~g}, 1 \mathrm{mmol})$ and the reaction mixture was left to stir at rt. After 72 h , the mixture was quenched with sat. (aq) $\mathrm{NH}_{4} \mathrm{Cl}$ ( 10 mL ), extracted with EtOAc ( 15 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (1:4-1:0, EtOAc:hexane, as eluent) afforded $\mathbf{5 0 7}$ as an orange solid ( $0.008 \mathrm{~g}, 4 \%$ ), $\mathbf{5 0 5}$ as an off-colourless solid ( $0.056 \mathrm{~g}, 27 \%$ ) and 506 as an off-colourless solid ( $0.126 \mathrm{~g}, 69 \%$ ): $R_{f} .0 .10$ ( $1: 1$, EtOAc:hexane, as eluent); m.p. 100-101 ${ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.22-8.18(\mathrm{~m}, 4 \mathrm{H}, H a), 7.56-$ 7.52 (m, 4H, $H b$ ), 5.36-5.30 (m, 2H, $H c$ ), 3.45 (br s, 2H, OH ), 2.98-2.81 (m, 4H, Hd) ppm (addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signal at $\delta 3.45$ to disappear); ${ }^{13} \mathrm{C}$ NMR ( 101 MHz , $\mathrm{CDCl}_{3}$ ) $\delta 209.4$ (209.3) (s, $C g$ ), 149.7 (149.8) (s, Ce), 147.7 (s, Cf), 126.5 (126.6) (d, $C a), 124.0$ (124.4) (d, Cb), 69.1 (69.2) (d, Cc), 51.9 (52.0) (t, Cd); IR $v_{\text {max }}$ (thin film) $3458(\mathrm{OH}), 1710(\mathrm{C}=\mathrm{O}), 1514(\mathrm{Ar}), 1343\left(\mathrm{NO}_{2}\right) \mathrm{cm}^{-1}$; LRMS (TOF ES-), 359.2 (55\%) [M-H], 208.0 ( $100 \%$ ), 149.0 (20\%); HRMS (TOF ES-), calculated for $\mathrm{C}_{17} \mathrm{H}_{15} \mathrm{~N}_{2} \mathrm{O}_{7}, 359.0879$; found 359.0887 . ${ }^{1} \mathrm{H}$ NMR spectroscopic properties were identical to those reported in the literature. ${ }^{285}$

## (2R,6S)-2,6-Bis(4-nitrophenyl)dihydro-2H-pyran-4(3H)-one ${ }^{286}$

507
To $473(0.039 \mathrm{~g}, 0.2 \mathrm{mmol})$ and triethylamine $(0.028 \mathrm{~mL}, 0.2 \mathrm{mmol})$ in acetone $(1 \mathrm{~mL})$ was added $p$-nitrobenzaldehyde $(0.151 \mathrm{~g}, 1 \mathrm{mmol})$ and the reaction mixture was left to stir at rt . After 72 h , the mixture was quenched with sat. (aq) $\mathrm{NH}_{4} \mathrm{Cl}$ $(10 \mathrm{~mL})$, extracted with EtOAc $(15 \mathrm{~mL})$, dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (1:4-1:0, EtOAc:hexane, as eluent) afforded 505 as an off-colourless solid ( $0.056 \mathrm{~g}, 27 \%$ ), $\mathbf{5 0 6}$ as an off-colourless solid ( 0.126 g , $69 \%$ ) and 507 as an orange solid ( $0.008 \mathrm{~g}, 4 \%$ ): $R_{f .} 0.27$ (1:1, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $700 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.31-8.28(\mathrm{~m}, 4 \mathrm{H}, \mathrm{Ha}), 7.66-7.63(\mathrm{~m}, 4 \mathrm{H}, \mathrm{Hb})$,

All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{208}$

## 1-(4-Chlorophenyl)-3-hydroxy-2-(hydroxy(4-nitrophenyl)methyl)-3-(4-nitrophenyl)propan-1-one

511

To $473(0.039 \mathrm{~g}, 0.2 \mathrm{mmol})$ and triethylamine $(0.028 \mathrm{~mL}, 0.2 \mathrm{mmol})$ in DMSO $(1 \mathrm{~mL})$ was added $p$-chloroacetophenone $(0.155 \mathrm{~g}, 1 \mathrm{mmol})$ and $p$-nitrobenzaldehyde $(0.151 \mathrm{~g}, 1 \mathrm{mmol})$ and the reaction mixture was left to stir at rt . After 216 h , the mixture was quenched with sat. (aq) $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$, extracted with EtOAc ( 15 mL ), dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (1:4-1:0, EtOAc:hexane, as eluent) afforded $\mathbf{5 1 0}$ as an off-colourless solid ( 0.009 g , $3 \%$ ) and $\mathbf{5 1 1}$ as an off-colourless solid ( $0.023 \mathrm{~g}, 5 \%$ ): ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 8.07-8.00 (m, 4H, Ha), 7.54-7.46 (m, 4H, Hb), 7.24-7.18 (m, 2H, He), 7.13-7.07 (m, $2 \mathrm{H}, H f$ ), 5.57-5.52 (m, 2H, Hc), 4.28 (br s, 2H, OH), 4.20-4.08 (m, 1H, Hd) ppm; LRMS (TOF ES+), 479.2 (80\%) [M+Na] ${ }^{+}, 304.4$ (40\%), 185.2 (40\%), 139.2 (50\%), 130.2 (100\%); HRMS (TOF ES+), calculated for $\mathrm{C}_{22} \mathrm{H}_{17} \mathrm{~N}_{2} \mathrm{O}_{7} \mathrm{Cl}+\mathrm{Na}^{+}$, 479.0622; observed 479.0623.
(3S,4R)-3-Hydroxy-4-((4-methoxyphenyl)amino)-4-(4-nitrophenyl)butan-2-one ${ }^{209}$

519

To $p$-anisidine ( $0.135 \mathrm{~g}, 1.1 \mathrm{mmol}$ ) and $p$-nitrobenzaldehyde ( $0.151 \mathrm{~g}, 1 \mathrm{mmol}$ ) in DMSO ( 8.1 mL ) was added hydroxyacetone ( $0.9 \mathrm{~mL}, 10 \mathrm{vol} \%$ ) and L-proline $(0.023 \mathrm{~g}, 0.2 \mathrm{mmol})$. The reaction mixture was stirred at rt overnight, quenched with
saturated (aq) $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$, diluted with $\mathrm{CHCl}_{3}(20 \mathrm{~mL})$ and separated with EtOAc $(3 \times 20 \mathrm{~mL})$ with the aid of brine $(10 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo to afford a crude oil. Purification by silica gel chromatography ( $4: 1$ to $2: 1$, hexane:EtOAc, as eluent) afforded 519 as an orange oil $(0.274 \mathrm{~g}, 83 \%): R_{f .} 0.46$ (2:1, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H} \mathrm{NMR}\left(400 \mathrm{MHz}, \mathrm{CDCl}_{3}\right)$ $\delta 8.17-8.13(\mathrm{~m}, 2 \mathrm{H}, \mathrm{He}), 7.56-7.53(\mathrm{~m}, 2 \mathrm{H}, H d), 6.69-6.65(\mathrm{~m}, 2 \mathrm{H}, H g), 6.48-6.44(\mathrm{~m}$, $2 \mathrm{H}, H f), 5.04(\mathrm{~d}, J=2.4 \mathrm{~Hz}, 1 \mathrm{H}, H b), 4.44(\mathrm{~d}, J=2.4 \mathrm{~Hz}, 1 \mathrm{H}, H c), 4.42(\mathrm{br} \mathrm{s}, 1 \mathrm{H}$, $\mathrm{N} H$ ), $3.99(\mathrm{br} \mathrm{s}, 1 \mathrm{H}, \mathrm{OH}), 3.66(\mathrm{~s}, 3 \mathrm{H}, H h), 2.36(\mathrm{~s}, 3 \mathrm{H}, H a) \mathrm{ppm}\left(\right.$ addition of $\mathrm{D}_{2} \mathrm{O}$ caused the signals at $\delta 4.42$ and 3.99 to disappear); ${ }^{13} \mathrm{C}$ NMR ( $101 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 206.7 (s, $C i$ ), 152.8 (s, $C m$ ), 147.5 (s, $C j$ ), 147.4 (s, $C k$ ), 139.3 (s, $C l$ ), 128.2 (d, $C d$ ), 123.8 (d, Ce), $115.2(\mathrm{~d}, C g), 115.0(\mathrm{~d}, C f), 80.0(\mathrm{~d}, C b), 58.8(\mathrm{~d}, C c), 55.6(\mathrm{~d}, C h)$, 25.0 (d, Ca); LRMS (TOF ES + ), 331.2 ( $50 \%$ ) $[\mathrm{M}+\mathrm{H}]^{+}, 257.3$ (100\%); HRMS (TOF ES+), calculated for $\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{~N}_{2} \mathrm{O}_{5}+\mathrm{H}^{+}$, 331.1294; observed 331.1300. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{209}$

## 4-((4-Methoxyphenyl)amino)-4-(4-nitrophenyl)butan-2-one ${ }^{288}$

520

To the $\mathbf{4 7 3}(0.2 \mathrm{mmol})$ and triethylamine $(0.028 \mathrm{~mL}, 0.2 \mathrm{mmol})$ in acetone $(1 \mathrm{~mL})$ was added $p$-nitrobenzaldehyde $(0.151 \mathrm{~g}, 1 \mathrm{mmol})$ and $p$-anisidine $(0.123 \mathrm{~g}, 1 \mathrm{mmol})$. The reaction mixture was stirred at rt overnight, quenched with (aq) $\mathrm{NH}_{4} \mathrm{Cl}(10 \mathrm{~mL})$ and extracted with EtOAc $(2 \times 10 \mathrm{~mL})$. The combined organics were dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography ( $10 \%-100 \%$, EtOAc:hexane, as eluent) afforded $\mathbf{3 2 6}$ as a yellow solid ( $0.075 \mathrm{~g}, 29 \%$ ), $\mathbf{3 5 5}$ as a beige solid $(0.015 \mathrm{~g}, 8 \%), \mathbf{5 0 5}$ as a yellow oil $(0.036 \mathrm{~g}, 17 \%), \mathbf{5 0 6}$ as an orange oil $(0.022 \mathrm{~g}, 12 \%)$ and 520 as a yellow oil $(0.020 \mathrm{~g}, 6 \%): R_{f .} 0.28$ (2:3, EtOAc:hexane, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.18-8.14(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ha}), 7.56-7.53(\mathrm{~m}, 2 \mathrm{H}, h b)$,
6.70-6.66 (m, 2H, Hf), 6.47-6.44 (m, 2H, Hg), $4.85(\mathrm{t}, J=6.3 \mathrm{~Hz}, 1 \mathrm{H}, H \mathrm{c}), 4.26(\mathrm{br} \mathrm{s}$, $1 \mathrm{H}, \mathrm{OH}), 3.69(\mathrm{~s}, 3 \mathrm{H}, H h), 2.94(\mathrm{~d}, j=6.3 \mathrm{~Hz}, 2 \mathrm{H}, H d), 2.15(\mathrm{~s}, 3 \mathrm{H}, H e) \mathrm{ppm},{ }^{13} \mathrm{C}$ NMR ( $151 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 206.2$ ( $\mathrm{s}, C k$ ), 152.9 (s, Cm), 150.8 (s, Cj), 147.3 ( $\left.\mathrm{s}, C i\right)$, 140.3 ( $\mathrm{s}, C l$ ), 127.5 (d, $C a$ ), 124.2 (d, $C b$ ), 115.5 (d, Cf), 114.9 (d, $C g$ ), 55.8 (d, Cc), $54.8(\mathrm{~d}, C h), 50.8(\mathrm{t}, C d), 30.8(\mathrm{~d}, C e)$. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{288}$

## 4-Dibenzylamino-2-butanone ${ }^{289}$

521

To dibenzylamine ( $0.59 \mathrm{~g}, 3 \mathrm{mmol}$ ) and phenylboronic acid ( $37 \mathrm{mg}, 0.3 \mathrm{mmol}$ ) dissolved in water ( 3 mL ) was added methyl vinyl ketone $(0.27 \mathrm{~mL}, 3.3 \mathrm{mmol})$ and the reaction mixture was stirred at rt overnight. The reaction mixture was extracted with EtOAc ( $3 \times 10 \mathrm{~mL}$ ), dried $\left(\mathrm{MgSO}_{4}\right)$ and concentrated in vacuo. Purification by silica gel chromatography (4:1, petroleum ether:diethyl ether, as eluent) afforded $\mathbf{5 2 1}$ as a white solid $(0.44 \mathrm{~g}, 55 \%)$ : m.p. $57-58{ }^{\circ} \mathrm{C}\left(\text { lit. } 59^{\circ} \mathrm{C}\right)^{290} ; R_{f} .0 .27$ (3:2, petroleum ether:diethyl ether, as eluent); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 7.35-7.21(\mathrm{~m}, 10 \mathrm{H}$, $\mathrm{Ar} H$ ), $3.55(\mathrm{~s}, 4 \mathrm{H}, H d), 2.77(\mathrm{t}, J=7 \mathrm{~Hz}, 2 \mathrm{H}, H b), 2.59(\mathrm{t}, J=7 \mathrm{~Hz}, 2 \mathrm{H}, H c), 1.99(\mathrm{~s}$, $3 \mathrm{H}, \mathrm{Ha}) \mathrm{ppm} ;{ }^{13} \mathrm{C}$ NMR (101 MHz, $\left.\mathrm{CDCl}_{3}\right) \delta 208.3(\mathrm{~s}, \mathrm{Ca}), 139.4$ ( $\left.\mathrm{s}, \mathrm{Ci}\right), 129.0(\mathrm{~d}$, Ar), 128.4 (d, Ar), 127.1 (d, Ar), 58.5 (t, Cd), 48.7 (t, Cc), 42.1 (t, Cb), 29.8 (d, Ca); IR $v_{\text {max }}$ (neat) $1698(\mathrm{C}=\mathrm{O}) \mathrm{cm}^{-1}$; LRMS (TOF ES + ), $268.2(100 \%)[\mathrm{M}+\mathrm{H}]^{+}$; HRMS (TOF ES+), calculated for $\mathrm{C}_{18} \mathrm{H}_{21} \mathrm{NO}+\mathrm{H}^{+}, 268.1701$; found 268.1706. All spectroscopic and analytical properties were identical to those reported in the literature. ${ }^{210,226}$

Chapter 7:
APPENDIX

## 7. Appendix

### 7.1 List of Publications

P. R. Girling, T. Kiyoi, A. Whiting, "Mannich-Michael versus formal aza-Diels-Alder approaches to piperidine derivatives", Org. Biomol. Chem., 2011, 9, 3105-3121.
P. R. Girling, A. S. Batsanov, H. C. Shen, A. Whiting, "A multicomponent formal $[1+2+1+2]$-cycloaddition for the synthesis of dihydropyridines", Chem. Commun., 2012, 48, 4893-4895.

### 7.2 List of Conferences Attended

| Date | Meeting | Location | Presentation |
| :---: | :---: | :---: | :---: |
| 12/01/2010 | Sheffield Stereochemistry | Sheffield |  |
| 26/01/2010 | Thomas Swan \& Co. Ltd. | Consett | - |
| 17/03/2010 | Life in the Biopharmaceutical Industry | Durham | - |
| 18/03/2010 | Catalyst Preparation 4 the $21^{\text {st }}$ Century | London | Poster |
| 15/04/2010 | RSC Organic Division Northeast Region Symposium | Durham | Poster |
| 22/04/2010 | RSC Bioorganic Meeting | Nottingham | Poster |
| $\begin{gathered} \text { 08/07/2010 - } \\ 09 / 07 / 2010 \end{gathered}$ | USIC (Universities of Scotland Inorganic Conference) | Durham | - |
| $\begin{aligned} & 13 / 10 / 2010- \\ & 15 / 10 / 2010 \end{aligned}$ | Dalton Discussion 12: Catalytic C-H and C-X Bond Activation | Durham | - |
| 28/10/2010 | $1^{\text {st }}$ NORSC (NORthern Sustainable Chemistry) Network Seminar Day | York | Poster |
| 13/01/2011 | Stereochemistry at Sheffield | Sheffield | - |
| 06/04/2011 | $22^{\text {nd }}$ SCI Graduate Symposium | Manchester | - |
| 13/04/2011 | RSC Organic Division Northeast Region Symposium | Northumbria | Poster |
| 15/04/2011 | RSC Bioorganic Group Postgraduate Symposium $22^{\text {nd }}$ SCI Regional Graduate | London | - |
| 03/05/2011 | Symposium on Novel Organic Chemistry | Edinburgh | - |
| 04/05/2011 | $2^{\text {nd }}$ Pre-Grasmere Symposium | York | - |
| 08/08/2011 | Merck Medicinal Chemistry Group Meeting | Rahway, New Jersey, USA | Oral |
| 16/08/2011 | Merck Summer-Intern Poster Symposium | Rahway, New Jersey, USA | Poster |
| $\begin{gathered} \text { 28/08/2011 - } \\ 01 / 09 / 2011 \end{gathered}$ | $242^{\text {nd }}$ ACS Fall Meeting 2011 | Denver, USA | - |
| 22/09/2011 | RSC Postgraduate Symposium: Heterocyclic and Synthesis Group | AstraZeneca, Alderley Park | Oral |

| 25/10/2011 | $2^{2^{\text {nd }}}$ NORSC Network Seminar | York | Oral |
| :---: | :---: | :---: | :---: |
| 02/11/2011 | Challenges in Catalysis III | London | Poster |
| 22/11/2011 | Durham Synthetic Seminar | Durham | Oral |
| $\begin{gathered} 07 / 12 / 2011- \\ 09 / 12 / 2011 \end{gathered}$ | $2^{\text {th }}$ SCI Process Development | Cambridge | - |
| 10/01/2012 | Stereochemistry at Sheffield | Sheffield | - |
| $\begin{gathered} \text { 25/03/2012 - } \\ 29 / 03 / 2012 \end{gathered}$ | $243^{\text {rd }}$ ACS National Meeting and | San Diego, USA | Oral |
| 12/04/2012 | $23^{\text {rd }}$ SCI Regional Graduate Symposium on Novel Organic Chemistry | Leeds | Oral |
| 24/04/2012 | NEPIC- NORSC Sustainable Chemistry for Industry Event | Ramside Hall, Durham |  |
| 13/06/2012 | Durham Postgraduate Symposium | Durham | Oral |
| 03/07/2012 | North West Organic Chemistry | Liverpool | Poster |
| $\begin{gathered} \text { 09/09/2012-13/09/2012 } \end{gathered}$ | 21st IUPAC International Conference on Physical Organic Chemistry | Durham | - |

## $7.3 \quad{ }^{1} \mathrm{H}^{-1} \mathrm{H}$ 2D NOE (NOESY) Spectrum

431

### 7.4 X-Ray Crystallography Data

## Crystallography Data for Compound $\mathbf{3 6 9}$

Table 1: Crystal data and structure refinement for 369

| Identification code | $\mathbf{3 6 9}$ |
| :---: | :---: |
| Empirical formula | $\mathrm{C}_{17} \mathrm{H}_{17} \mathrm{NO}_{2}$ |
| Formula weight | 267.32 |
| Temperature $/ \mathrm{K}$ | 120.0 |
| Crystal system | orthorhombic |
| Space group | Pbca |
| $\mathrm{a} / \AA, \mathrm{b} / \AA, \mathrm{c} / \AA$ | $10.5511(4), 8.8537(3), 28.6974(10)$ |
| $\alpha /^{\circ}, \beta /^{\circ}, \gamma /{ }^{\circ}$ | $90.00,90.00,90.00$ |
| Volume $/ \AA^{3}$ | $2680.80(17)$ |
| Z | 8 |
| $\rho_{\text {calc }} / \mathrm{mg} \mathrm{mm}^{-3}$ | 1.325 |
| $\mu / \mathrm{mm}^{-1}$ | 0.087 |
| $\mathrm{~F}(000)$ | 1136 |
| Crystal size $/ \mathrm{mm}^{3}$ | $0.04 \times 0.12 \times 0.20$ |
| Theta range for data collection | $1.42 \mathrm{to} 49.98^{\circ}$ |
| Index ranges | $-12 \leq \mathrm{h} \leq 12,-10 \leq \mathrm{k} \leq 10,-34 \leq 1 \leq 34$ |
| Reflections collected | 25682 |
| Independent reflections | $2369[\mathrm{R}(\mathrm{int})=0.0883]$ |
| Data/restraints $/$ parameters | $2369 / 0 / 249$ |

$$
\begin{array}{cc}
\text { Goodness-of-fit on } \mathrm{F}^{2} & 0.945 \\
\text { Final R indexes [I>2 } \sigma(\mathrm{I})] & \mathrm{R}_{1}=0.0377, \mathrm{wR}_{2}=0.0812 \\
\text { Final R indexes [all data] } & \mathrm{R}_{1}=0.0734, \mathrm{wR}_{2}=0.0946 \\
\text { Largest diff. peak/hole } / \mathrm{e} \AA^{-3} & 0.178 /-0.191 \\
\hline
\end{array}
$$

Table 2 Fractional Atomic Coordinates $\left(\times 10^{4}\right)$ and Equivalent Isotropic Displacement Parameters $\left(\AA^{2} \times 10^{3}\right)$ for $\mathbf{3 6 9}$. $U_{\text {eq }}$ is defined as $1 / 3$ of of the trace of the orthogonalised $\mathrm{U}_{\mathrm{IJ}}$ tensor.

| Atom | $x$ | $y$ | $z$ | U(eq) |
| :---: | :---: | :---: | :---: | :---: |
| O1 | 6631.7(12) | 1694.5(14) | 5105.4(5) | 27.3(4) |
| O 2 | 6609.5(13) | 6731.9(15) | 6678.0(5) | 30.8(4) |
| N | 3834.6(14) | 5204.5(17) | 5791.1(5) | 19.3(4) |

[^0]:    * Single X-ray structures obtained.
    \# An inseparable mixture of cycloadduct and its MeOH adduct was obtained in ca. 3:1 ratio in an estimated yield (by ${ }^{1} \mathrm{H}$ NMR) of $39 \%$.
    NB: The reactions could have gone to completion before the times stated in the table, the table merely states when they were purified by silica gel chromatography.

    At first glance, this reaction looks similar to the Hantzsch pyridine synthesis; ${ }^{185}$ however, it almost certainly proceeds through a novel and different mechanism in order to give rise to the different dihydropyridines. The use of an enone instead of an $\alpha$-ketoester to form these types of dihydropyridines is almost unprecedented; to our knowledge, only Inouye et al. reported in the late 1950s the only related example, ${ }^{186,}$

[^1]:    $\dagger$ Not all of the catalyst was in solution.

    * Equimolar amounts of $\mathrm{NEt}_{3}$ were added to neutralise the catalyst.
