# Error Analysis and Stability of Numerical Schemes for Initial Value problems "IVP's" 

By

Imad Omar Faris Kayid

Supervised

Prof. Naji Qatanani

This Thesis is Submitted in Partial Fulfillment of the Requirements for the Degree of Master of Computational Mathematics, Faculty of Graduate Studies, An-Najah National University, Nablus, Palestine.

# Error Analysis and Stability of Numerical Schemes for Initial Value problems "IVP's" 

By<br>Imad Omar Faris Kayid

This thesis was defended successfully on 7/2/2013 and approved by:

## Defense Committee Members

1-Prof. Dr. Naji Qatanani (Supervisor)
2-Dr. Yousef Zahaykah (External Examiner)
3-Dr. Subhi Ruzieh
(Internal Examiner)

Signature
N. Gatanani

## Dedication

I would like to dedicate this thesis to my parents, to my wife Raifa, who supported me each step of the way and to my children Yara, Kareem and Noor.

## Acknowledgment

First of all, I would thank my supervisor Prof. Dr. Naji Qatanani for his efforts and important guidance for the completion of this thesis.

# Error Analysis and Stability of Numerical Schemes for Initial Value problems "IVP's" 

## By

Imad Omar Faris Kayid<br>Supervisor

## Prof. Dr. Naji Qatanani

## Abstract

Most of initial value problems are natural phenomena written in the language of mathematics. Solving these initial value problems is one of the most challenging fields in mathematics, because of the mathematicians' continuous desire of exactness.

This work focuses mainly on developing algorithms and programs to construct higher order Taylor's methods for approximating the solution of first order initial value problems, systems of first order initial value problems and higher order initial value problems. Moreover, it concentrates on studying error and stability of numerical methods for solving initial value problems. For this purpose, we developed programs to find the error amplification functions of Taylor's and Runge-Kutta methods and to plot boundaries of stability regions for these methods and other methods.

We concluded that with the programs we developed, higher order Taylor's methods could be a good choice for approximating solutions of a wide range

## Introduction

Many problems in engineering and science can be formulated in terms of differential equations. Many mathematicians have studied the nature of these equations and many complicated systems can be described exactly with compact mathematical expressions.

The techniques for solving differential equations based on numerical approximations were developed before programmable computers existed. The problem of solving ordinary differential equations is classified into initial value and boundary value problems, depending on the conditions specified at the end points of the domain.

There are numerous methods that produce numerical approximations to the solution of initial value problems in ordinary differential equations such as Euler's method which was the oldest and simplest method originated by Leonard Euler in 1768. He was the first who suggested the idea to propagate the solution of an initial value problem by a sequence of small time-steps. In each step, the rate of change of the solution is treated as constant and is found from the formula for the derivative evaluated at the beginning of the step [5]. An improved Euler's method and Runge-Kutta methods described by Carl Runge and Martin Kutta in 1895 and 1905 respectively. The paper by Runge is now recognized as the starting point for modern one-step methods [6].

The 1883 paper of Bashforth and Adams [1] and the 1926 paper of Moulton [14] were the foundation blocks of developing multistep methods. Through their work, the explicit Adams-Bashforth methods, the implicit AdamsMoulton methods and the predictor-corrector methods were established. Milne also contributed in this field by the methods called after him and by the socalled Milne's device, which estimates error in predictor-corrector methods [13].

Numerical methods form an important part of solving initial value problems in ordinary differential equations most especially in cases where there is no closed form solution.

This thesis is organized as follows:
Chapter one gives perspective study of differential equations in particular, initial value problems, systems of first order initial value problems and higher order initial value problems.

In chapter two we introduce some numerical examples for solving initial value problems. These include single step methods and multistep methods.

Chapter three deals with higher order Taylor methods for solving first order IVP's, systems of first order IVP's and higher order IVP's.

In chapter four some error analysis for the numerical methods: Taylor method, Runge-Kutta method, Adams-Bashforth method, Adams-Moulton method, predictor-corrector method and Milne's method will be investigated and presented through same numerical examples.

## Chapter One

## Initial Value Problem

### 1.1 Preliminaries

A differential equation: is an equation relating some function $f$ to one or more of its derivatives.

The equation
$\frac{d y}{d t}=y(t)-t^{2}+3$
is a differential equation.
The order of a differential equation is the order of the highest derivative that appears in the equation.

The equation

$$
\mathrm{y}^{\prime \prime}-2 \mathrm{y}^{\prime}+\mathrm{y}=\mathrm{t} e^{t}-\mathrm{t}
$$

is of order 2 .
The degree of an ordinary differential equation: is the greatest number of times the dependent variable appears in any single term. For example, the degree of $y^{\prime}+\left(y^{\prime \prime}\right)^{2} y+1=0$ is 3 , whereas the degree of $y^{\prime \prime} y^{\prime} y^{2}+x^{5} y=1$ is 4 .

An ordinary differential equation (ODE): is an equation with the derivatives of a function of one variable.

The general form of an explicit $k$ th order ordinary differential equation is given by
$y^{(k)}=f\left(t, y, y^{\prime}, \ldots, y^{(k-1)}\right)$
where $\mathrm{y}, \mathrm{y}^{\prime}, \ldots, \mathrm{y}^{(\mathrm{k}-1)}$ are functions of t .
The general solution of this equation contains $k$ arbitrary constants $c_{1}, c_{2}, \ldots, c_{k}$. These constants can be found by prescribing $k$ conditions.

A partial differential equation (PDE) describes a relation between an unknown function and its partial derivatives.

The heat equation
$\frac{\partial u}{\partial t}-\alpha^{2}\left(\frac{\partial^{2} u}{\partial x^{2}}+\frac{\partial^{2} u}{\partial y^{2}}+\frac{\partial^{2} u}{\partial z^{2}}\right)=0$
is a second order PDE.
Initial value problem (IVP): is a problem that specifies the initial conditions at the same value of $t$.

As an example
$\mathrm{y}^{\prime \prime}=y+2 e^{t}, \quad y(0)=0, \quad y^{\prime}(0)=1$
is an initial value problem since both conditions imposed on $t=0$.
Boundary value problem: is a problem that specifies the boundary conditions at different values of $\boldsymbol{t}$.

As an example
$\mathrm{y}^{\prime \prime}=y+2 e^{t}, \quad y(0)=0, \quad y^{\prime}(1)=e$.
is a boundary value problem because the two conditions are specified at different values of $t$.

### 1.2 Initial Value Problem (IVP)

A first order initial value problem defined on the interval $[a, b]$ can be written as
$\frac{d y}{d t}=f(t, y(t)) \quad a \leq t \leq b, \quad y(a)=\alpha$
Since any ordinary differential equation of order $k$
$y^{(k)}=f\left(t, y, y^{\prime}, \ldots, y^{(k-1)}\right)$
can always be transformed into a system of $k$ first-order equations, we will focus on solving first order initial value problems and systems of first order initial value problems.

### 1.3 Existence and Uniqueness of the Solution

Solving differential equations can be done by two major ways. The first way is to find the exact solution analytically. The other way is to approximate the solution by numerical methods at usually equally spaced points, then interpolate the solution to the whole interval of interest. Since most differential equations that represent real nature phenomena cannot be solved analytically, we will focus on solving initial value problems using numerical approximations.

Before we discuss methods for approximating the solution to our basic problem (1.2), we must consider some theory to ensure that our problem has a unique solution and know how small errors on the initial condition can affect the accuracy of the approximated solution.

## Definition (1.1)

A function $f(t, y)$ is said to satisfy a Lipschitz condition in the variable $y$ on a set $D \subset \mathbb{R}^{2}$ if a constant $L>0$ exists with

$$
\left|f\left(t, y_{1}\right)-f\left(t, y_{2}\right)\right| \leq L\left|y_{1}-y_{2}\right|,
$$

whenever $\left(t, y_{1}\right)$ and $\left(t, y_{2}\right)$ are in $D$. The constant $L$ is called a Lipschitz constant for $f$ [3].

Example (1.1) We can show that $f(t, y)=t y^{2}$ satisfies a Lipschitz condition on the set $D=\{(t, y): 1 \leq t \leq 2$ and $1 \leq y \leq 3\}$.

For each pair of points $\left(t, y_{1}\right)$ and $\left(t, y_{2}\right)$ in D we have

$$
\begin{aligned}
\left|f\left(t, y_{1}\right)-f\left(t, y_{2}\right)\right| & =\left|t y_{1}^{2}-t y_{2}^{2}\right|=|t|\left|y_{1}^{2}-y_{2}^{2}\right| \\
& =|t|\left|y_{1}+y_{2}\right|\left|y_{1}-y_{2}\right| \\
& \leq 2 \times 6 \times\left|y_{1}-y_{2}\right|=12\left|y_{1}-y_{2}\right| .
\end{aligned}
$$

Thus, $f$ satisfies a Lipschitz condition on $D$ in the variable $y$ with a Lipschitz constant $L=12$.

Definition (1.2) [16]
A set $D \subset \mathbb{R}^{n}$ is said to be convex if, whenever $\boldsymbol{x}$ and $\boldsymbol{y}$ belong to $D$, also $\theta x+(1-\theta) y \in D \quad \forall \theta \in[0,1]$.

Thus, a set $D \subset \mathbb{R}^{2}$ is convex if $\left(t_{1}, y_{1}\right),\left(t_{2}, y_{2}\right) \in D$ then the point

$$
\lambda\left(t_{1}, y_{1}\right)+(1-\lambda)\left(t_{2}, y_{2}\right) \in D \text { with } \lambda \in[0,1] .
$$

Since a line segment between $\left(t_{1}, y_{1}\right)$ and $\left(t_{2}, y_{2}\right)$ is the set of all points $(t, y)=\lambda\left(t_{1}, y_{1}\right)+(1-\lambda)\left(t_{2}, y_{2}\right) \quad \lambda \in[0,1]$, then a set $D$ in $\mathbb{R}^{2}$ is called a convex set if the line segment joining any pair of points of $D$ lies entirely in $S$.

The set S in Figure (1.1) (a) is convex because the line segment joining any pair of points of $S$ lies entirely in $S$, while the set D in Figure (1.1) (b) is nonconvex, since points a and b lie in D , but the line segment $\overline{a b}$ does not lie entirely in D.

(a)

(b)

Figure(1.1): (a) Convex Set S. (b) Non-convex Set D.

## Example (1.2)

We can show that the set $D=\{(t, y): a \leq t \leq b$ and $-\infty \leq y \leq \infty\}$ is convex.
$\operatorname{Let}\left(t_{1}, y_{1}\right),\left(t_{2}, y_{2}\right) \in D$.
So, $a \leq t_{1} \leq b$ and $a \leq t_{2} \leq b$.
For $\lambda \in[0,1]$
$(1-\lambda) a \leq(1-\lambda) t_{1} \leq(1-\lambda) b$ and $\lambda a \leq \lambda t_{2} \leq \lambda b$.
These two inequalities give
$a \leq(1-\lambda) t_{1}+\lambda t_{2} \leq b$.
It is obvious that
$-\infty \leq(1-\lambda) y_{1}+\lambda y_{2} \leq \infty$.
Therefore, D is a convex set.
Theorem (1.1) [3]
Suppose $f(t, y)$ is defined on a convex set $D \subset \mathbb{R}^{2}$. If a constant $L>0$ exists
with
$\left|\frac{\partial f}{\partial y}(t, y)\right| \leq L, \quad$ for all $(t, y) \in D$,
then $f$ satisfies a Lipschitz condition on $D$ in the variable y with a Lipschitz constant $L$.

Proof: Holding $t$ constant and applying the Mean Value Theorem to the function $f(t, y)$, when $y_{1}<y_{2}$, a number $\xi$ in $\left(y_{1}, y_{2}\right)$ exists with

$$
\begin{aligned}
& \frac{f\left(t, y_{2}\right)-f\left(t, y_{1}\right)}{y_{2}-y_{1}}=\frac{\partial f}{\partial y}(t, \xi), \\
& \left|f\left(t, y_{2}\right)-f\left(t, y_{1}\right)\right|=\left|y_{2}-y_{1}\right|\left|\frac{\partial f}{\partial y}(t, \xi)\right| \leq\left|y_{2}-y_{1}\right| L .
\end{aligned}
$$

Thus, $f$ satisfies a Lipschitz condition on $D$ in the variable $y$ with a Lipschitz constant $L$.

## Example (1.3)

For the set $D=\{(t, y): 1 \leq t \leq 2$ and $-\infty \leq y \leq \infty\}$ it easy to show, that $f(t, y)=t y$ satisfies a Lipschitz condition in the variable $y$.

We have shown in Example (1.2) that D is convex. In addition $\left|\frac{\partial f}{\partial y}(t, y)\right|=|t| \leq 2$.

Thus $f$ satisfies a Lipschitz condition on $D$ in the variable y with a Lipschitz constant 2.

## Definition (1.3) [3]

The initial value problem
$\frac{d y}{d t}=f(t, y(t)), \quad a \leq t \leq b, \quad y(a)=\alpha$,
is said to be a well-posed problem if:

- A unique solution, $y(t)$ to the problem exists, and
- There exist constants $\varepsilon_{0}>0$ and $\mathrm{k}>0$ such that for any $\varepsilon$, with $\varepsilon_{0}>\varepsilon>0$, whenever $\delta(t)$ is continuous with $|\delta(\mathrm{t})|<\varepsilon$ for all $t$ in $[\mathrm{a}, \mathrm{b}]$, and when
$\left|\delta_{0}\right|<\varepsilon$ the initial-value problem
$\frac{d z}{d t}=f(t, z)+\delta(t), a \leq t \leq b, \quad z(a)=\alpha+\delta_{0}$.
has a unique solution $\mathrm{z}(\mathrm{t})$ that satisfies

$$
|z(t)-y(t)|<k \varepsilon \text { for all } t \text { in }[a, b] .
$$

Point two in this definition says that small perturbations of the original problem and small perturbations of the initial condition have only small error effects on the approximated solution. To illustrate this we give the following example.

## Example (1.4)

Using definition (1.3), we can show that the initial value problem
$y^{\prime}(t)=y(t)+1, \quad 0 \leq t \leq 1,, y(0)=0$
is well-posed.
Consider the perturbed problem with constant $\delta$ and $\delta_{0}$
$z^{\prime}(t)=z(t)+1+\delta, \quad 0 \leq t \leq 1, \quad z(0)=\delta_{0}$.
$y(t)=e^{t}-1 \quad$ and $z(t)=\left(\delta+\delta_{0}+1\right) e^{t}-(1+\delta)$.
Suppose that $\varepsilon>0$. And if $|\delta|<\varepsilon$ and $\left|\delta_{0}\right|<\varepsilon$, then
$|z(t)-y(t)|=\left|\left(\delta+\delta_{0}\right) e^{t}-\delta\right|$
$\leq\left|\left(\delta+\delta_{0}\right) e^{t}\right|+|\delta| \leq 2 \varepsilon e^{1}+\varepsilon=(2 e+1) \varepsilon$,
for all $t$. Therefore, the problem is well-posed with $k=(2 e+1)$ and for all $\varepsilon>0$.

The next theorem tells us sufficient conditions that guarantee well posedness of our basic problem.

## Theorem (1.2) [3]

Suppose that $D=\{(t, y): a \leq t \leq b$ and $-\infty<y<\infty\}$. If $f(t, y)$ is continuous and satisfies a Lipschitz condition in the variable $y$ on the set $D$, then the initial value problem
$y^{\prime}(t)=f(t, y), a \leq t \leq b, \quad y(a)=\alpha$,
is well-posed.
We note, that this theorem ensures the uniqueness of the solution $y(t)$ for $a \leq t \leq b$.

## Example (1.5)

We can show that the IVP
$y^{\prime}=t^{2} y+1, \quad 0 \leq t \leq 2, \quad y(0)=1$,
is well-posed.
The function $f(t, y)=t^{2} y+1$ is continuous. We have shown in Example (1.2) that the set $D=\{(t, y): 0 \leq t \leq 2$ and $-\infty<y<\infty\}$ is convex. In addition, we have

$$
\left|\frac{\partial f}{\partial y}(t, y)\right|=\left|t^{2}\right| \leq 4
$$

Thus $f$ satisfies a Lipschitz condition on $D$ in the variable $y$ with Lipschitz constant 4. Therefore, according to theorem (1.2) the IVP is well-posed.

## Theorem (1.3) [4]

Suppose that $f$ and $f_{y}$, its first partial derivative with respect to $y$, are continuous for $t$ in $[a, b]$ and for all $y$. Then the initial value problem

$$
\frac{d y}{d t}=f(t, y(t)), \quad a \leq t \leq b \quad \text { and } \quad y(a)=\alpha,
$$

has a unique solution $y(t)$ for $a \leq t \leq b$, and the problem is well-posed.
Proof: The set $D=\{(t, y): a \leq t \leq b$ and $-\infty<y<\infty\}$ is convex. Since $f_{y}$ is continuous on $[\mathrm{a}, \mathrm{b}]$, then $f_{y}$ is bounded. Therefore, there exists a real number $L>0$ such that $\left|f_{y}\right| \leq L$. Thus, $f$ satisfies a Lipschitz condition on D in the variable $y$. Also $f$ is continuous. It follows from theorem (1.2), that the IVP is well-posed.

## Example (1.6)

The initial-value problem

$$
y^{\prime}=\left(t-0.5 t^{2}\right)+y, \text { for } 0 \leq t \leq 1 \text { and } y(0)=1
$$

is a well-posed initial value problem, since the functions

$$
f(t, y)=\left(t-0.5 t^{2}\right)+y, \text { and } f_{y}(t, y)=1
$$

are both continuous for $0 \leq t \leq 2$ and for all y .

### 1.4 Systems of First Order Initial Value Problems

A $k$ th-order system of first order initial value problems has the general form $u_{1}^{r}=f_{1}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{k}}\right)$ $u_{2}^{r}=f_{2}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{k}}\right)$
$\vdots$
$u_{k}^{r}=f_{k}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{k}}\right)$
for $a \leq t \leq b$, with the initial conditions

$$
\begin{equation*}
\mathrm{u}_{1}(\mathrm{a})=\alpha_{1}, \mathrm{u}_{2}(\mathrm{a})=\alpha_{2}, \ldots, \mathrm{u}_{\mathrm{k}}(\mathrm{a})=\alpha_{\mathrm{k}} \tag{1.3}
\end{equation*}
$$

To solve this system we must find $\mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{k}}$ that satisfy all the differential equations and the initial conditions.

Consider the following system of IVP's

$$
\begin{aligned}
& \mathrm{u}_{1}^{I}(\mathrm{t})=\mathrm{u}_{2}(\mathrm{t}) \\
& \mathrm{u}_{2}^{I}(\mathrm{t})=2 \mathrm{u}_{1}(\mathrm{t})+\mathrm{u}_{2}(\mathrm{t})
\end{aligned}
$$

together with the initial conditions

$$
\mathrm{u}_{1}(0)=8 \text { and } \mathrm{u}_{2}(0)=4 .
$$

We can show that

$$
\mathrm{u}_{1}(\mathrm{t})=4 \mathrm{e}^{2 \mathrm{t}}+4 \mathrm{e}^{-\mathrm{t}}, \quad \mathrm{u}_{2}(\mathrm{t})=8 \mathrm{e}^{2 \mathrm{t}}+4 \mathrm{e}^{-\mathrm{t}}
$$

is the solution of this system.
Solving this system numerically will be discussed in next chapter.

### 1.5 Higher Order Initial Value Problem

The first step to solve an IVP of order k

$$
\begin{align*}
& y^{(k)}=f\left(t, y, y^{\prime}, y^{\prime \prime}, \ldots, y^{(k-1)}\right), \quad a \leq t \leq b \\
& y(a)=\alpha_{1}, y^{\prime}(a)=\alpha_{2}, y^{\prime \prime}(a)=\alpha_{3}, \ldots, y^{(k-1)}(a)=\alpha_{k} . \tag{1.4}
\end{align*}
$$

is to transform it into a system of first order IVP as follows:
Let

$$
\mathrm{u}_{1}=\mathrm{y},
$$

$$
\begin{align*}
& \mathrm{u}_{2}=\mathrm{y}^{\prime}, \\
& \mathrm{u}_{3}=\mathrm{y}^{\prime \prime} \\
& \vdots \\
& \mathrm{u}_{\mathrm{k}}=\mathrm{y}^{(\mathrm{k}-1)} . \tag{1.5}
\end{align*}
$$

Differentiating these equations, we get

$$
\begin{align*}
& \mathrm{u}_{1}^{\prime}=\mathrm{y}^{\prime}, \\
& \mathrm{u}_{2}^{\prime}=\mathrm{y}^{\prime \prime}, \\
& \mathrm{u}_{3}^{\prime}=\mathrm{y}^{\prime \prime \prime}, \\
& \vdots \\
& \mathrm{u}_{\mathrm{k}}^{\prime}=\mathrm{y}^{(\mathrm{k})}=f\left(\mathrm{t}, \mathrm{y}, \mathrm{y}^{\prime}, \mathrm{y}^{\prime \prime}, \ldots, \mathrm{y}^{(\mathrm{k}-1)}\right) \tag{1.6}
\end{align*}
$$

Substituting we get a system of first order IVP

$$
\begin{align*}
& \mathrm{u}_{1}^{\prime}=\mathrm{u}_{2} \\
& \mathrm{u}_{2}^{\prime}=\mathrm{u}_{3} \\
& \vdots \\
& \mathrm{u}_{\mathrm{k}-1}^{\prime}=\mathrm{u}_{\mathrm{k}} \\
& \mathrm{u}_{\mathrm{k}}^{\prime}=f\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{k}}\right) . \\
& \mathrm{u}_{1}(\mathrm{a})=\mathrm{y}(\mathrm{a})=\alpha_{1}, \mathrm{u}_{2}(\mathrm{a})=\mathrm{y}^{\prime}(\mathrm{a})=\alpha_{2}, \ldots, \mathrm{u}_{\mathrm{k}}(\mathrm{a})=\mathrm{y}^{(\mathrm{k}-1)}(\mathrm{a})=\alpha_{\mathrm{n}} . \tag{1.7}
\end{align*}
$$

The second step is to solve this system for $u_{1}, \ldots, u_{k}$ satisfying (1.6). Finally, the solution of $u_{1}$ is assigned to $y$ because $y=u_{1}$.

To illustrate this method, consider the following example.

## Example (1.7)

We will show how to transform the following second order IVP into a
two-dimensional system of first order IVP's:

$$
y^{\prime \prime}-2 y^{\prime}+y=\mathrm{te}^{\mathrm{t}}-\mathrm{t}, \quad 0 \leq \mathrm{t} \leq 1,
$$

with initial conditions

$$
\mathrm{y}(0)=0, \quad \mathrm{y}^{\prime}(0)=0 .
$$

First, we rewrite the DE as

$$
y^{\prime \prime}=2 y^{\prime}-y+t^{t}-t .
$$

Now let

$$
\begin{aligned}
& u_{1}=y, \\
& u_{2}=y^{\prime} .
\end{aligned}
$$

Differentiating both equations with respect to $t$, we get

$$
\begin{aligned}
& \mathrm{u}_{1}^{r}=\mathrm{y}^{\prime}, \\
& \mathrm{u}_{2}^{r}=\mathrm{y}^{\prime \prime} .
\end{aligned}
$$

Substituting, we get a system of first order IVP's

$$
\begin{aligned}
& \mathrm{u}_{1}^{\prime}=\mathrm{u}_{2}, \\
& \mathrm{u}_{2}^{\prime}=2 \mathrm{u}_{2}-\mathrm{u}_{1}+\mathrm{te}^{\mathrm{t}}-\mathrm{t}
\end{aligned}
$$

with initial conditions
$\mathrm{u}_{1}(0)=\mathrm{y}(0)=0, \quad \mathrm{u}_{2}(0)=\mathrm{y}^{\prime}(0)=0$.
Solving systems of IVP's numerically will be discussed next chapter.

## Chapter Two

## Numerical Methods for Initial Value Problems

### 2.1 Introduction

In this chapter, we shall study some numerical methods for solving IVP's of the form
$y^{\prime}(t)=f(t, y(t)), \quad a \leq t \leq b, \quad y(a)=\alpha$,
that possess a unique solution on some specified interval, $t \in[a, b]$. In these numerical methods, we will find approximations to the solution of the initial value problem at N particular equally spaced points

$$
t_{i+1}=t_{i}+h, \quad i=1, \ldots, N, N=\left[\frac{b-a}{h}\right], \quad t_{1}=a, y\left(t_{1}\right)=\alpha,
$$

approximations to the numbers $y\left(t_{2}\right), \ldots, y\left(t_{N+1}\right)$, rather than to the curve of $y(t)$.

Methods for approximating the solution of initial value problems can be classified mainly into two types. They are
(i) Single step methods,
(ii) Multistep methods.

Both of these methods can be either implicit or explicit. If the approximate solution $\mathrm{w}_{\mathrm{i}+1}$ depends only on the previous $w_{j}, j=1, \ldots, i$, then the method is explicit. However, if $w_{i+1}$ depends on $w_{i+1}$ too, then the method is implicit, that is, we get an algebraic equation for the solution of $w_{i+1}$.

### 2.2 Single Step methods

In single step methods, the solution at any point $t_{i+1}$ is obtained by using the solution at only the previous point $t_{\mathrm{i}}$. Thus, we can write a general implicit single step method as
$w_{i+1}=w_{i}+h \varphi\left(t_{i+1}, w_{i+1}, t_{i}, w_{i}, h\right)$,
and a general explicit single step method as
$w_{i+1}=w_{i}+h \varphi\left(t_{i}, w_{i}, h\right)$,
where $\varphi$ is a function of the arguments $t_{i}, w_{i}, h$ and depends on $f(t, y(t))$ of the given differential equation. The function $\varphi$ is called the increment function, see [10].

## Definition (2.1) (Local Truncation Error) [9]

The local truncation error $\tau_{i+1}$ of a method is defined to be the difference between the exact and the numerical solution of the IVP at time $t=t_{i+1}$ :
$\tau_{i+1}=y\left(t_{i+1}\right)-w_{i+1}$,
under the localizing assumption that $w_{i}=y\left(t_{i}\right)$, i.e. that the current numerical solution $w_{i}$ is exact. If $\tau_{i+1}=O\left(h^{p+1}\right)(p>0)$, the method is said to be of order p .

If we calculate $\widehat{w}_{i+1}$ assuming $w_{i}=y_{i}$, that is:
$\widehat{w}_{i+1}=y_{i}+h \varphi\left(t_{i}, y_{i}, h, f\right)$,
then the LTE, $\tau_{i+1}$, at $t_{i+1}$ is defined by:
$\tau_{i+1}=y_{i+1}-\widehat{w}_{i+1}$
$\tau_{i+1}=y_{i+1}-y_{i}-h \varphi\left(t_{i}, y_{i}, h, f\right)$.

## Definition (2.2)

The global truncation error: The difference
$e_{i}=y\left(t_{i}\right)-w_{i}$
is referred to as the global error (GE) at $\mathrm{t}=\boldsymbol{t}_{i}$.

## Definition (2.3) [3]

A one-step difference-equation method with local truncation error $\tau_{i}(h)$ at the $i$ th step is said to be consistent with the differential equation it approximates if
$\lim _{h \rightarrow 0} \max _{1 \leq i \leq N}\left|\tau_{i}(h)\right|=0$.
Definition (2.4) [9]
A numerical method is said to converge to the solution $y(t)$ of a given IVP at $t=t^{*}$ if the GE $e_{i}=y\left(t_{i}\right)-w_{i}$ at $t_{i}=t^{*}=t_{0}+i h$ satisfies $\left|e_{i}\right| \rightarrow 0$
as $h \rightarrow 0$. It converges at a $p$ th-order rate if $e_{i}=O\left(h^{p}\right)$ for some $p>0$.
A numerical method is said to be consistent of order p if

$$
\tau_{i+1}=O\left(h^{p+1}\right) \text { with } p>0
$$

Before we begin our discussion of the methods, we shall first derive the Taylor series expansion of $y\left(t_{i+1}\right)$ with remainder.

## Theorem (2.1) (Taylor Theorem) [2]

Suppose $f$ has $n+1$ continuous derivatives on an open interval containing $a$.
Then for each $x$ in the interval,

$$
f(x)=\left[\sum_{k=0}^{n} \frac{f^{(k)}(a)}{k!}(x-a)^{k}\right]+R_{n+1}(x)
$$

where the error term $R_{n+1}(x)$ satisfies
$R_{n+1}(x)=\frac{f^{(n+1)}(c)}{(n+1)!}(x-a)^{n+1}$
for some $c$ between $a$ and $x$.
Now for our Problem (1.2), if $y(t)$ is continuous and has $n+1$ continuous derivatives on an interval about $t=t_{i}$, then the Taylor series expansion of $y(t)$ about $t=t_{i}$ is
$y(t)=\sum_{p=0}^{\infty}\left(\frac{y^{(p)}\left(t_{i}\right)}{p!}\left(t-t_{i}\right)^{p}\right)$
Now, for $t=t_{i+1}, t_{i+1}-t_{i}=h$, therefore (2.4) becomes
$y_{i+1}=y_{i}+h y_{i}^{I}+\frac{1}{2} h^{2} y_{i}^{\prime \prime}+\cdots+\frac{1}{n!} h^{n} y_{i}^{(n)}+R_{n+1}(t)$
$y_{i+1}=y_{i}+h\left[y_{i}^{\prime}+\frac{1}{2} h y_{i}^{\prime \prime}+\cdots+\frac{1}{n!} h^{n-1} y_{i}^{(n)}\right]+R_{n+1}(t)$
$R_{n+1}(t)=\frac{1}{(n+1)!} h^{n+1} y^{(n+1)}(c), \quad c \in\left(t_{i}, t_{i+1}\right)$
When $y^{\prime}(t)=f(t, y(t))$, we can replace $y_{i}^{(j+1)}$ by $f_{i}^{(j)}$ in the previous equations for $j=0, \ldots, n$.

We note that the expression in the square brackets in (2.6) represents the $(n-1)$ Taylor expansion of $f(t, y)$.

Finally, in (2.6) if we let
$T^{(n)}\left(t_{i}, y_{i}, h\right)=\left[y_{i}^{\prime}+\frac{1}{2} h y_{i}^{\prime \prime}+\cdots+\frac{1}{n!} h^{n-1} y_{i}^{(n)}\right]$,
then (2.6) becomes

$$
\begin{equation*}
y_{i+1}=y_{i}+h T^{(n)}\left(t_{i}, y_{i}, h\right)+R_{n+1}(t) . \tag{2.9}
\end{equation*}
$$

### 2.2.1 Euler's Method

Euler was the first who suggested the idea to propagate the solution of an initial value problem forward by a sequence of small time-steps. In each step, the rate of change of the solution is treated as constant and is found from the formula for the derivative evaluated at the beginning of the step [5].

One way to derive Euler's method for approximating the solution of the first order IVP (1.2) is achieved by approximating $y_{i}^{I}=f\left(t_{i}, y_{i}\right)$ as follows:
$f\left(t_{i}, y_{i}\right) \approx \frac{y_{i+1}-y_{i}}{h}$.
Solving for $y_{i+1}$, we get
$y_{i+1} \approx y_{i}+h f\left(t_{i}, y_{i}\right)$.
Using this equation, we get Euler's forward method
$w_{i+1}=w_{i}+h f\left(t_{i}, w_{i}\right)$.
Now, if $f$ is differentiable on $(a, b)$ and $f^{\prime}$ is continuous on $[a, b]$, then there exists $c \in\left[t_{i}, t_{i+1}\right]$ such that
$y_{i+1}=y_{i}+h f\left(t_{i}, y_{i}\right)+\frac{1}{2} h^{2} f^{\prime}(c, y(c))$.
To find the LTE of Euler's method, we have $\widehat{W}$ as defined in (2.2)

$$
\widehat{w}_{i+1}=y_{i}+h f\left(t_{i}, y_{i}\right),
$$

therefore

$$
\begin{aligned}
\tau_{i+1} & =y_{i+1}-y_{i}-h f\left(t_{i}, y_{i}\right), \\
\tau_{i+1} & =\frac{1}{2} h^{2} f^{\prime}(c, y(c)) .
\end{aligned}
$$

Then, if a positive number $M$ exists so that $\left|f^{\prime}(t, y)\right| \leq M$ for all $t \in(a, b)$, then
$\left|\tau_{i+1}\right| \leq \frac{1}{2} M h^{2} \quad \tau_{i+1}=O\left(h^{2}\right)$.
It follows from Definition (2.1) that Euler's method is of order $O(h)$.
We introduce now Algorithm (2.1) for approximating the solution of the problem (1.2) using Euler's method and comparing the approximated solution with the exact solution.

## Algorithm (2.1): Euler's Method.

| Step 1: | Define $f(t, y), y \operatorname{Exact}(t)$ |
| :--- | :--- |
| Step 2: | Input $a, b, \alpha, h$ |
| Step 3: | Let $N=(b-a) / h$ |
| Step 4: | Let $w_{1}=\alpha, t_{1}=a, y_{1}=\alpha$ |
| Step 5: | For $i=1$ to $N$ |
|  | $\quad w_{i+1}=w_{i}+h f\left(t_{i}, w_{i}\right)$ |
|  | $\quad y_{i+1}=y E x a c t\left(t_{i+1}\right)$ |
| Step 6: | $t_{i+1}=t_{i}+h$ |
| Step 7: | Find GE $=a b s(y-w)$ |
| Step 8: |  |
|  | Output $t, y, w, G E$ |
|  | Stop |

## Example (2.1)

Consider Euler's method to approximate the solution of the following initialvalue problem:
$y^{\prime}=\frac{y}{t}-\left(\frac{y}{t}\right)^{2}, 1 \leq t \leq 2, \quad y(1)=1$, using $h=0.1$.
This initial value problem has the exact solution
$y(t)=\frac{t}{\log (t)+1}$.
Matlab Program (2.1)(See Appendix A) is an implementation of Algorithm (2.1) in computer language. The results of running this program for our Example (2.1) are represented in Table (2.1). In addition to the approximated solution of $y(t)$, at each step the program calculates the absolute values of the global error $e$ (column 4) and the local truncation error $\tau$ (column 6). It also plots (Figure (2.1)) the approximated vector $w$ (column 3) and the exact vector $y$ (column 2) against the vector $t$ (column 1).

Table (2.1): Results of Example (2.1) using Euler's method with $\mathbf{h}=\mathbf{0} .1$

| $t_{i}$ | $y_{i}$ | $w_{i}$ | $a b s\left(y_{i}-w_{i}\right)$ | $\widehat{w}_{i}$ | $a b s\left(\tau_{i}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1.0000000 | 1.0000000 | 1.0000000 | 0.0000000 | 1.0000000 | 0.0000000 |
| 1.1000000 | 1.0042817 | 1.0000000 | 0.0042817 | 1.0000000 | 0.0042817 |
| 1.2000000 | 1.0149523 | 1.0082645 | 0.0066879 | 1.0122262 | 0.0027261 |
| 1.3000000 | 1.0298137 | 1.0216895 | 0.0081242 | 1.0279950 | 0.0018187 |
| 1.4000000 | 1.0475339 | 1.0385147 | 0.0090192 | 1.0462776 | 0.0012562 |
| 1.5000000 | 1.0672624 | 1.0576682 | 0.0095942 | 1.0663717 | 0.0008907 |
| 1.6000000 | 1.0884327 | 1.0784611 | 0.0099716 | 1.0877888 | 0.0006439 |
| 1.7000000 | 1.1106551 | 1.1004322 | 0.0102229 | 1.1101830 | 0.0004721 |
| 1.8000000 | 1.1336536 | 1.1232621 | 0.0103915 | 1.1333041 | 0.0003494 |
| 1.9000000 | 1.1572284 | 1.1467236 | 0.0105048 | 1.1569686 | 0.0002599 |
| 2.0000000 | 1.1812322 | 1.1706516 | 0.0105806 | 1.1810389 | 0.0001934 |

We notice that the results are consistent with the theoretical error estimates for Euler's method, since the global error is of $O(h)$ and the local truncation error is of $O\left(h^{2}\right)$.

If we repeat solving Example (2.1), but using $h=0.05$ instead of $h=0.1$, we get better results. Table (2.2) shows that the global error at the last step
using $\mathrm{h}=0.05$ is 0.0051070 , while it was 0.0105806 (Table 2.1) when we used $h=0.1$.

In addition, we notice that

$$
\frac{0.0051070}{0.0105806}=0.4826758 \approx\left(\frac{0.05}{0.1}\right)^{1}=0.5
$$

which agrees with our theoretical analysis that Euler's method is of $O(h)$.
If we do the same for the local truncation error, we get
$\frac{0.0000437}{0.0001934}=0.2259565 \approx\left(\frac{0.05}{0.1}\right)^{2}=0.25$
which agrees with our theoretical analysis that local truncation error for Euler's method is of $O\left(h^{2}\right)$.

Table (2.2): Results of Example (2.1) using Euler's method with $\mathbf{h = 0 . 0 5}$

| 1.5000000 | 1.0672624 | 1.0626605 | 0.0046019 | 1.0670633 | 0.0001990 |
| 1.5500000 | 1.0776949 | 1.0729880 | 0.0047068 | 1.0775256 | 0.0001693 |
| 1.6000000 | 1.0884327 | 1.0836401 | 0.0047926 | 1.0882881 | 0.0001446 |
| 1.6500000 | 1.0994318 | 1.0945687 | 0.0048630 | 1.0993078 | 0.0001239 |
| 1.7000000 | 1.1106551 | 1.1057341 | 0.0049209 | 1.1105486 | 0.0001065 |
| 1.7500000 | 1.1220713 | 1.1171026 | 0.0049686 | 1.1219796 | 0.0000916 |
| 1.8000000 | 1.1336535 | 1.1286457 | 0.0050078 | 1.1335746 | 0.0000790 |
| 1.8500000 | 1.1453792 | 1.1403389 | 0.0050402 | 1.1453110 | 0.0000681 |
| 1.9000000 | 1.1572285 | 1.1521615 | 0.0050669 | 1.1571697 | 0.0000588 |
| 1.9500000 | 1.1691843 | 1.1640954 | 0.0050889 | 1.1691337 | 0.0000507 |
| 2.0000000 | 1.1812322 | 1.1761253 | 0.0051070 | 1.1811885 | 0.0000437 |

Figure (2.1) compares the approximated solutions with the exact solutions of Example (2.1). It is clear that Euler's method is not accurate for our choice of the step size $h=0.1$ (Figure (2.1):(a)). To get better results, we have to make h smaller, and that means more computation time, or to find another more accurate method. Figure (2.1) (b) shows that the approximated solution gets closer to the exact solution when we use smaller values of h .

Figure (2.1) Comparison between the approximated solution and the exact solution of Example (2.1) (a): using $h=0.1 \quad$ (b) using $h=0.05$.

### 2.2.2 Runge-Kutta Methods

Runge-Kutta methods are based on the 1895 paper of C. Runge [15] and the 1901 paper of W. Kutta [11]. The paper by Runge is now recognized as the starting point for modern one-step methods [6].

The family of explicit Runge-Kutta methods is given by
$w_{n+1}=w_{n}+\sum_{i=1}^{s} b_{i} k_{i}$,
where
$k_{1}=h f\left(t_{n}, w_{n}\right)$,

$$
\begin{aligned}
k_{2}= & h f\left(t_{n}+c_{2} h, w_{n}+a_{21} k_{1}\right) \\
k_{3}= & h f\left(t_{n}+c_{3} h, w_{n}+a_{31} k_{1}+a_{32} k_{2}\right) \\
& \vdots \\
k_{s}= & h f\left(t_{n}+c_{s} h, w_{n}+a_{s 1} k_{1}+a_{s 2} k_{2}+\cdots+a_{s, s-1} k_{s-1}\right)[7] .
\end{aligned}
$$

To specify a particular method, one needs to provide the integer $s$ (the number of stages), and the coefficients $a_{i j}($ for $1 \leq j<i \leq s), b_{i}($ for $i=1,2, \ldots, s)$ and $c_{i}($ for $i=2,3, \ldots, s)$. The matrix $\left[a_{i j}\right]$ is called the Runge-Kutta matrix, while the $b_{i}$ and $c_{i}$ are known as the weights and the nodes. These data are usually arranged in a mnemonic device, known as a Butcher tableau (after John C. Butcher):

| 0 |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $c_{2}$ | $a_{21}$ |  |  |  |  |
| $c_{3}$ | $a_{31}$ | $a_{32}$ |  |  |  |
| $\vdots$ |  |  | $\ddots$ |  |  |
| $c_{s}$ | $a_{s 1}$ | $a_{s 2}$ | $\cdots$ | $a_{s, s-1}$ |  |
|  | $b_{1}$ | $b_{2}$ | $\cdots$ | $b_{s-1}$ | $b_{s}$ |

Figure (2.2):Butcher tableau for explicit RK methods [7]

The Runge-Kutta method is consistent if (see [7])
$\sum_{j=1}^{s} b_{j}=1$ and $\sum_{j=1}^{i-1} a_{i j}=c_{i}$ for $i=2, \ldots, s$.
Figures (2.3) contains some Butcher tableaus for Runge-Kutta explicit methods. We can use any of these tableaus in Algorithm (2.2) to generate the desired Runge-Kutta method.

Figure (2.3) (e) Butcher tableau for classical explicit RK4 method [7]

We will use Taylor expansion

$$
\begin{align*}
& y_{i+1}=\left(y_{i}+h y_{i}^{\prime}+\frac{1}{2} h^{2} y_{i}^{\prime \prime}+\cdots+\frac{1}{6} h^{3} y_{i}^{\prime \prime \prime}+\cdots\right)_{t_{i}} \\
& =y_{i}+h f_{i}+\frac{h^{2}}{2}\left(f_{t}+f f_{y}\right)_{t_{i}} \\
& \quad+\frac{h^{3}}{6}\left(f_{t t}+2 f f_{t y}+f^{2} f_{y y}+f_{t} f_{y}+f f_{y}^{2}\right)_{t_{i}}+\cdots \tag{2.11}
\end{align*}
$$

to study two stages Runge-Kutta methods:

$$
\begin{align*}
y_{i+1} & =y_{i}+b_{1} k_{1}+b_{2} k_{2}  \tag{2.12}\\
k_{1}= & h f_{i} \\
k_{2}= & h f\left(t_{i}+c_{2} h, y_{i}+a_{21} h f_{i}\right) \\
= & h\left[f_{i}+\left(c_{2} h f_{t}+a_{21} h f f_{y}\right)_{t_{i}}\right. \\
& \left.+\frac{1}{2}\left\{\left(c_{2} h\right)^{2} f_{t t}+2 c_{2} h . a_{21} h f f_{t y}+\left(a_{21} h f\right)^{2} f_{y y}\right\}_{t_{i}}+\cdots\right] \\
= & h f_{i}+h^{2}\left(c_{2} f_{t}+a_{21} f f_{y}\right)_{t_{i}} \\
& +\frac{h^{3}}{2}\left\{\left(c_{2}\right)^{2} f_{t t}+2 c_{2} a_{21} f f_{t y}+a_{21}^{2} f^{2} f_{y y}\right\}_{t_{i}}+\cdots
\end{align*}
$$

Substituting the values of $k_{1}$ and $k_{2}$ in (2.12), we get

$$
\begin{align*}
& y_{i+1}=y_{i}+\left(b_{1}+b_{2}\right) h f_{i}+h^{2}\left(b_{2} c_{2} f_{x}+b_{2} a_{21} f f_{y}\right)_{t_{i}} \\
& +\frac{h^{3}}{2} b_{2}\left\{\left(c_{2}\right)^{2} f_{t t}+2 c_{2} a_{21} f f_{t y}+a_{21}^{2} f^{2} f_{y y}\right\}_{t_{i}}+\cdots \tag{2.13}
\end{align*}
$$

Comparing the coefficients of $h$ and $h^{2}$, we get
$b_{1}+b_{2}=1, \quad b_{2} c_{2}=\frac{1}{2}, \quad b_{2} a_{21}=\frac{1}{2}$.
Solving these equations, we get
$a_{21}=c_{2}, \quad b_{2}=\frac{1}{2 c_{2}}, \quad b_{1}=1-\frac{1}{2 c_{2}}$.
Using these values, we get the two stages Runge-Kutta methods

$$
\begin{aligned}
& w_{i+1}=w_{i}+\left(1-\frac{1}{2 c_{2}}\right) k_{1}+\frac{1}{2 c_{2}} k_{2} \\
& k_{1}=h f\left(t_{i}, w_{i}\right) \\
& k_{2}=h f\left(t_{i}+c_{2} h, w_{i}+c_{2} k_{1}\right)
\end{aligned}
$$

To find the local truncation error, we first substitute the values of $a_{21}, b_{1}$ and $b_{2}$ in equation (2.13). So we get

$$
\begin{align*}
y_{i+1}= & y_{i}+h f_{i}+\frac{h^{2}}{2}\left(f_{t}+f f_{y}\right)_{t_{i}} \\
& +\frac{h^{3}}{2}\left\{\frac{c_{2}}{2} f_{t t}+c_{2} f f_{x y}+\frac{c_{2}}{2} f^{2} f_{y y}\right\}_{t_{i}}+\cdots \\
= & y_{i}+h f_{i}+\frac{h^{2}}{2}\left(f_{t}+f f_{y}\right)_{t_{i}} \\
& +\frac{c_{2} h^{3}}{4}\left\{f_{t t}+2 f f_{t y}+f^{2} f_{y y}\right\}_{t_{i}}+\cdots \tag{2.14}
\end{align*}
$$

Subtracting (2.14) from (2.11), we get

$$
\begin{equation*}
\tau_{i+1}=h^{3}\left[\left(\frac{1}{6}-\frac{c_{2}}{4}\right)\left\{f_{t t}+2 f f_{t y}+f^{2} f_{y y}\right\}+\frac{1}{6}\left(f_{t} f_{y}+f f_{y}^{2}\right)+\cdots\right]_{t_{i}} . \tag{2.15}
\end{equation*}
$$

Therefore, we have local truncation error equals to $O\left(h^{3}\right)$ and hence the methods are of order two.

If we choose $c_{2}=2 / 3$, then the first term in brackets in (2.15) vanishes and we get a method with minimum local truncation error:
$k_{1}=h f\left(t_{i}, w_{i}\right)$,
$k_{2}=h f\left(t_{i}+\frac{2}{3} h, w_{i}+\frac{2}{3} k_{1}\right)$,
$w_{i+1}=w_{i}+\frac{1}{4}\left(k_{1}+3 k_{2}\right)$.
We employed Algorithm (2.2) to approximate the solution of first order IVPs using any RK explicit method. We enter the IVP, number of stages, s and the desired RK method (Butcher tableau) that agrees with s. In the next example, we will use the classical fourth order RK method (Figure (2.3) (e)).

Algorithm (2.2): Runge-Kutta explicit methods.

```
Step 1: Define f(t,y), yEx(t)
Step 2: Input endpoints a,b;initial condition a;step size h
Step 3: Input number of stages s
Step 4: Input Butcher matrix in A,B,C
Step 5:
Step 6: Let N=(b-a)/h
Step 7: Let w
Step 8: For n=1 to N repeatsteps 8-18
Step 9: Let sum1 =0
Step 10:
Step 11:
Let sum2 = 0
Step 13: }\quad\mathrm{ For j=1 to i-1 repeat step 12
Step 15: }\quad\operatorname{sum}2=\operatorname{sum}2+A(i,j)*k(j
Step 16: }\quadk(i)=h*f(t(n)+C(i)*h,w(n)+sum2
```

```
Step 17: }\quad\operatorname{sum}1=\operatorname{sum}1+B(i)*k(i
Step 18: w(n+1)=w(n)+\operatorname{sum}1
Step 19: t(n+1) =t(n)+h
Step 20: y(n+1)=fEx}(t(n+1)
Step 21
    Find GE =abs(y-w)
    Output t, y,w,GE
    Stop
```

We translated Algorithm (2.2) into a Matlab Program (2.2), which we will use to approximate the solution of the IVP and compare the approximate solution $w$ with the exact solution $y$.

## Example (2.2)

We can approximate the solution to the initial value problem
$y^{\prime}=-2 t y^{2}, t \in[0,1], \quad y(0)=1$.
using the fourth order classical Runge-Kutta method with $h_{1}=0.1$ and for $h_{2}=0.05$.

This initial value problem has the exact solution
$y(t)=1 /\left(1+t^{2}\right)$.
We represented the results of running Program (2.2) for this problem in Table (2.3) and Figure (2.4). We see that the results of this method are better than the results of Euler's method.

In addition, Table (2.3) shows that the global errors at $t=1$ are $6.0221055 \mathrm{E}-$
07 and 4.0931106E-08 for $h_{1}=0.1$ and $h_{2}=0.05$ respectively.

Straight forward computation of the ratio for these global errors we obtain
$\frac{4.0931106 E-08}{6.0221055 E-07}=0.0679681 \approx\left(\frac{0.05}{0.1}\right)^{4}=.0625$,
which agrees with Runge-Kutta of $\mathrm{O}\left(\mathrm{h}^{4}\right)$.

Figure (2.4) shows how close the approximate solution w and the exact solution are.

Figure (2.4): Comparison between the approximated solution and exact solution of Example (2.2) using $h_{1}=\mathbf{0 . 1}$

### 2.2.3 Taylor Methods

To derive Taylor methods to solve the initial value problem (1.2), we consider equations (2.5),(2.6),(2.7) and (2.8). These equations give us Taylor methods of order $n$
$w_{i+1}=w_{i}+h T^{(n)}\left(t_{i}, w_{i}, h\right)$,
where
$T^{(n)}\left(t_{i}, y_{i}, h\right)=y_{i}^{\prime}+\frac{1}{2} h y_{i}^{\prime \prime}+\cdots+\frac{1}{n!} h^{n-1} y_{i}^{(n)}$
and local truncation error at $t=t_{i+1}$
$\tau_{i+1}=R_{n+1}(c)=\frac{1}{(n+1)!} h^{n+1} y^{(n+1)}(c) \quad c \in(a, b)$,
and, if $\mid y\left({ }^{(n+1)}(t) \mid \leq M\right.$ for all $\mathrm{t} \in(\mathrm{a}, \mathrm{b})$, then

$$
\left|\tau_{i+1}\right| \leq \frac{\mathrm{M}}{(\mathrm{n}+1)!} \mathrm{h}^{\mathrm{n}+1},
$$

that is

$$
\tau_{i+1}=O\left(h^{n+1}\right) \text { and the method is } O\left(h^{n}\right) .
$$

## Example (2.3)

We can apply Taylor's method of orders two and six to the next initial value problem using step size $h=0.2$.

$$
y^{\prime}=y-t^{2}+1,0 \leq t \leq 2, y(0)=0.5
$$

This initial value problem has the exact solution
$y(t)=(t+1)^{2}-0.5 e^{t}$.
Results of running Program (3.3) for this problem are represented in Table (2.4) and Figure (2.5). The exact solution y is given in column 2, approximate solution and global error using second order Taylor method in columns 3 and 4, and finally approximated solution and global error using sixth order Taylor method in columns 5 and 6 . It is clear we have better results using higher order Taylor methods with the same step size.

In Figure (2.3), we have a closer look to see what happens at the last step. Comparing Figures (2.5) (a) and (b), we see that w and y in (a) are not so close as in (b). That means we have better results with higher order Taylor
methods.
Table (2.4): Results of Example (2.3) using Taylor's methods 2 and 6 with $h=0.2$

| $\mathrm{t}_{\mathrm{i}}$ | $\mathrm{y}_{\mathrm{i}}$ | $\mathrm{n}=2$ <br> $\mathrm{~W}_{\mathrm{i}}$ | error $_{\mathrm{i}}$ | $\mathrm{n}=6$ <br> $\mathrm{~W}_{\mathrm{i}}$ | error $_{\mathrm{i}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.0000000 | 0.5000000 | 0.5000000 | $0.0000000 \mathrm{E}+00$ | 0.5000000 | $0.0000000 \mathrm{E}+00$ |
| 0.2000000 | 0.8292986 | 0.8300000 | $7.0137909 \mathrm{E}-04$ | 0.8292986 | $1.3023073 \mathrm{E}-09$ |

| 1.6000000 | 4.2834838 | 4.3061464 | $2.2662606 \mathrm{E}-02$ | 4.2834838 | $4.2248928 \mathrm{E}-08$ |
| 1.8000000 | 4.8151763 | 4.8462986 | $3.1122332 \mathrm{E}-02$ | 4.8151763 | $5.8053327 \mathrm{E}-08$ |

| 2.0000000 | 5.3054720 | 5.3476843 | $4.2212341 \mathrm{E}-02$ | 5.3054720 | $7.8784993 \mathrm{E}-08$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
|  |  |  |  |  |  |

Figure (2.5): Results of Example (2.3) with h=0.2 (a) Taylor 2 (b) Taylor 6
Table (2.4) shows that the global error at $t=2$ is $7.8784993 \mathrm{E}-08$ for $\mathrm{n}=6$ and $\mathrm{h}=0.2$. We solved the same problem with $\mathrm{n}=6$ and $\mathrm{h}=0.05$. We found that the global error at $t=2$ is $1.3433343 \mathrm{E}-009$

We notice that
$\frac{1.3433343 E-009}{7.8784993 E-08}=0.017051 \approx\left(\frac{0.1}{0.2}\right)^{6}=0.015625$
which agrees with the theoretical error estimate for sixth order Taylor method which is equal $O\left(h^{6}\right)$.

### 2.3 Multistep Methods

The 1883 paper of Bashforth and Adams [1] and the 1926 paper of Moulton [14] were the foundation blocks of developing multistep methods. Through
their work, the explicit Adams-Bashforth methods, the implicit AdamsMoulton methods and the predictor-corrector methods were established. Milne also contributed in this field by the methods called after him and by the socalled Milne's device, which estimates error in predictor-corrector methods, see [13].

Multistep methods use the solution at a number of previous points to find the solution at any point $t_{i+1}$. If we use $w_{i}, w_{i-1}, \ldots, w_{i-m+1}, f\left(t_{i}, w_{i}\right)$,
$f\left(t_{i-1}, w_{i-1}\right), \ldots, f\left(x_{i-m+1}, w_{i-m+1}\right)$
at $m$ previous points $t_{i}, t_{i-1}, \ldots, t_{i-m+1}$ to find the approximation $w_{i+1}$ to $y(t)$ at $t_{i+1}$, then we call the method as an $m$-step multistep method.

For example, the method

$$
w_{i+1}=w_{i}+h \varphi\left(t_{i}, t_{i-1}, t_{i-2}, w_{i}, w_{i-1}, w_{i-2}, h\right),
$$

is a three step method.
We can write a general explicit m -step method as [10]

$$
\begin{equation*}
w_{i+1}=w_{i-r}+h \varphi\left(t_{i-m+1}, \ldots, t_{i-1}, t_{i}, w_{i-m+1}, \ldots, w_{i-1}, w_{i}, h\right), \tag{2.17}
\end{equation*}
$$

where $\quad r \in\{0,1, \ldots, m-1\}, \quad i=m, m+1, \ldots, N$.
If the right hand side contains $w_{i+1}$, then we have an implicit method.
To construct multi-step methods, we first integrate the differential equation $y^{\prime}=f(t, y)$
in the interval $\left[t_{i-r}, t_{i+1}\right]$, getting $\int_{t_{i-r}}^{t_{i+1}} d y=\int_{t_{i-r}}^{t_{i+1}} f(t, y) d t$
$y\left(t_{i+1}\right)=y\left(t_{i-r}\right)+\int_{t_{i-r}}^{t_{i+1}} f(t, y) d t[10]$.
We will use Newton's backward difference interpolating polynomial to approximate the integrand $f(x, y)$.

### 2.3.1 Predictor Methods

An m-step predictor method is an m-step explicit method defined in (2.17). If we use Newton's backward difference interpolating polynomial of degree $m-1$ to approximate the integrand $f(x, y)$ in the interval $\left[t_{i-r}, t_{i+1}\right]$.

For equally spaced $m$ points, $t_{i}, t_{i-1}, \ldots, t_{i-m+1}$, we get degree $m-1$ Newton's backward difference interpolating polynomial of $f(t, y)$, [3]

$$
\begin{align*}
& P_{m-1}(t)=\sum_{k=0}^{m-1}(-1)^{k}\binom{-s}{k} \nabla^{k} f\left(t_{i}, y_{i}\right)  \tag{2.19}\\
& f(t, y)=P_{m-1}(t)+\frac{f^{m}\left(\xi_{\mathrm{i}}, y\left(\xi_{\mathrm{i}}\right)\right)}{m!}\left(t-t_{i}\right)\left(t-t_{i-1}\right) \ldots\left(t-t_{i-m+1}\right) . \tag{2.20}
\end{align*}
$$

Now, for $t=t_{i}+s h$ we get

$$
\left(t-t_{i}\right)=s h,\left(t-t_{i-1}\right)=h(s+1), \ldots,\left(t-t_{i-m+1}\right)=h(s+m-1)
$$

Therefore,

$$
\begin{equation*}
\left(t-t_{i}\right)\left(t-t_{i-1}\right) \ldots\left(t-t_{i-m+1}\right)=h^{m} s(s+1) \ldots(s+m-1) . \tag{2.21}
\end{equation*}
$$

Substituting (2.19), (2.20), (2.21) and $r=0$ in (2.18), we get

$$
\begin{aligned}
y\left(t_{i+1}\right) & =y\left(t_{i}\right)+\int_{t_{i}}^{t_{i+1}} f(t, y(t)) d t \\
& =y\left(t_{i}\right)+\int_{t_{i}}^{t_{i+1}} \sum_{k=0}^{m-1}(-1)^{k}\binom{-s}{k} \nabla^{k} f\left(t_{i}, y_{i}\right) d t
\end{aligned}
$$

$$
\begin{gathered}
+\int_{t_{i}}^{t_{i+1}} \frac{f^{(m)}\left(\xi_{\mathrm{i}}, y\left(\xi_{\mathrm{i}}\right)\right)}{m!}\left(t-t_{i}\right)\left(t-t_{i-1}\right) \ldots\left(t-t_{i-m+1}\right) d t \\
= \\
=y\left(t_{i}\right)+h \sum_{k=0}^{m-1}\left[\nabla^{k} f\left(t_{i}, y\left(t_{i}\right) \int_{0}^{1}(-1)^{k}\binom{-s}{k} d s\right]\right. \\
\\
+\frac{h^{m+1}}{m!} f^{(m)}\left(\xi_{\mathrm{i}}, y\left(\xi_{\mathrm{i}}\right)\right) \int_{0}^{1} s(s+1) \ldots(s+m-1) d s \\
\left(\nabla f_{i}=f_{i}-f_{i-1} \text { and } \nabla^{k} f_{i}=\nabla^{k-1} f_{i}-\nabla^{k-1} f_{i-1}\right) .
\end{gathered}
$$

This leads to the m-step explicit Adams-Bashforth methods,
$w_{i+1}=w_{i}+h \sum_{k=0}^{m-1}\left[\nabla^{k} f\left(t_{i}, w_{i}\right) \int_{0}^{1}(-1)^{k}\binom{-s}{k} d s\right]$.
with local truncation error

$$
\begin{equation*}
\left|\tau_{i}\right|<\frac{M h^{m+1}}{m!} \int_{0}^{1} s(s+1) \ldots(s+m-1) d s \tag{2.23}
\end{equation*}
$$

Therefore, $\tau_{i}=O\left(h^{m+1}\right)$ and the methods are $O\left(h^{m}\right)$.
Now, we compute the coefficients $\int_{0}^{1}(-1)^{k}\binom{-s}{k} d s$.
For $k=0, \int_{0}^{1}(-1)^{0}\binom{-s}{0} \mathrm{ds}=\int_{0}^{1} d s=1$.
For $k=1, \int_{0}^{1}(-1)^{1}\binom{-s}{1} \mathrm{ds}=\int_{0}^{1}(-1)(-s) d s=\int_{0}^{1} s d s=\frac{1}{2}$.
For $k=2, \int_{0}^{1}(-1)^{2}\binom{-s}{2} \mathrm{~d} s=\frac{1}{2!} \int_{0}^{1}(-s)(-s-1) d s=\frac{1}{2!} \int_{0}^{1} s(s+1) d s=\frac{5}{12}$.
For $k=3, \int_{0}^{1}(-1)^{3}\binom{-s}{3} \mathrm{~d} s=\frac{1}{3!} \int_{0}^{1} s(s+1)(s+2) d s=\frac{9}{24}$.
For $k=4, \int_{0}^{1}(-1)^{4}\binom{-s}{4} d s=\frac{1}{4!} \int_{0}^{1} s(s+1)(s+2)(s+3) \mathrm{d} s=\frac{251}{720}$.
$\vdots$
For $k=k, \int_{0}^{1}(-1)^{k}\binom{-s}{k} d s=\frac{1}{k!} \int_{0}^{1} s(s+1)(s+2)(s+k-1) \mathrm{d} s$.
We used Matlab Program (2.3) to compute these integrals for $k=1, \ldots, 10$ and represented the results in Table (2.5). Using these results, (2.22) becomes

$$
w_{i+1}=w_{i}+h\left[f_{i}+\frac{1}{2} \nabla f_{i}+\frac{5}{12} \nabla^{2} f_{i}+\frac{3}{8} \nabla^{3} f_{i}+\frac{251}{720} \nabla^{4} f_{i}+\cdots\right]
$$

For $m=1, k=0$

$$
w_{i+1}=w_{i}+h f_{i}
$$

Table (2.5): Coefficients of Adams-Bashforth methods

| k | $\int_{0}^{1}(-1)^{k}\binom{-s}{k} d s$ |
| :---: | :--- |
| 0 | 1 |
| 1 | $1 / 2$ |
| 2 | $5 / 12$ |
| 3 | $3 / 8$ |
| 4 | $251 / 720$ |
| 5 | $95 / 288$ |
| 6 | $19087 / 60480$ |
| 7 | $5257 / 17280$ |
| 8 | $1070017 / 3628800$ |
| 9 | $25713 / 89600$ |
| 10 | $26842253 / 95800320$ |

For $m=2, k=0,1$
$w_{i+1}=w_{i}+h\left[f_{i}+\frac{1}{2} \nabla f_{i}\right]=w_{i}+h\left[f_{i}+\frac{1}{2}\left(f_{i}-f_{i-1}\right)\right]$
$w_{i+1}=w_{i}+\frac{h}{2}\left[3 f_{i}-f_{i-1}\right]$
For $m=3, k=0,1,2$
$w_{i+1}=w_{i}+h\left[f_{i}+\frac{1}{2} \nabla f_{i}+\frac{5}{12} \nabla^{2} f_{i}\right]$

$$
\begin{aligned}
& =w_{i}+h\left[f_{i}+\frac{1}{2}\left(f_{i}-f_{i-1}\right)+\frac{5}{12} \nabla\left(f_{i}-f_{i-1}\right)\right] \\
& =w_{i}+h\left[f_{i}+\frac{1}{2}\left(f_{i}-f_{i-1}\right)+\frac{5}{12}\left(\left(f_{i}-f_{i-1}\right)-\left(f_{i-1}-f_{i-2}\right)\right]\right. \\
& =w_{i}+h\left[\frac{23}{12} f_{i}-\frac{16}{12} f_{i-1}+\frac{5}{12} f_{i-2}\right] \\
& w_{i+1}=w_{i}+\frac{h}{12}\left[23 f_{i}-16 f_{i-1}+5 f_{i-2}\right] .
\end{aligned}
$$

For $m=4, k=0,1,2,3$ we find in the same way that
$w_{i+1}=w_{i}+h\left[f_{i}+\frac{1}{2} \nabla f_{i}+\frac{5}{12} \nabla^{2} f_{i}+\frac{3}{8} \nabla^{3} f_{i}\right]$
$w_{i+1}=w_{i}+\frac{h}{24}\left[55 f_{i}-59 f_{i-1}+37 f_{i-2}-9 f_{i-3}\right]$.
The method in (2.24) is the 4-step Adam-Bashforth method, for which we wrote Algorithm (2.3) to approximate first order IVP (1.2). It uses RK4 to approximate the solution at $t_{2}, t_{3}, t_{4}$, where $t_{1}=a$ and $y\left(t_{1}\right)=\alpha$.

Algorithm (2.3): Adams-Bashforth 4-step method using RK4 to find the starting points

| Step 1: | Define $f(t, y), y E x(t)$ |
| :--- | :--- |
| Step 2: | Input endpoints $a, b ;$ initial condition $\alpha ;$ step size $h$ |
| Step 3: | Let number of steps $N=(b-a) / h$ |
| Step 4: | Let $t_{1}=a_{i}$ |
| Step 5: | Let $w_{1}=\alpha ;$ The vector $w$ contains the approximad solution of $y$ |
| Step 6: | Let $y_{1}=\alpha ;$ The vector $y$ contains the exact solution of $y$ |
| Step 7: | For $i=1$ to $N$ repeat steps $8-15$ |
| Step 8: | $\quad k_{1}=f\left(t_{i}, w_{i}\right)$ |
| Step 9: | $k_{2}=f\left(t_{i}+1 / 2 h, w_{i}+1 / 2 h k_{1}\right)$ |
| Step 10: | $k_{3}=f\left(t_{i}+1 / 2 h, w_{i}+1 / 2 h k_{2}\right)$ |
| Step 11: | $k_{4}=f\left(t_{i}+h, w_{i}+h k_{3}\right)$ |
| Step 12: |  |
| Step 13: |  |

```
Step 15: \(\quad w_{i+1}=w_{i}+h / 6\left(k_{1}+2 k_{2}+2 k_{3}+k_{4}\right)\)
Step 16: \(\quad t_{i+1}=t_{i}+h\)
Step 17: \(\quad y_{i+1}=y E x\left(t_{i+1}\right)\)
    For \(i=4\) to \(N\) repeat steps \(17-19\)
Step 18:
Step 19:
Step 20:
Step 21: \(\quad t_{i+1}=t_{i}+h\)
Step22: \(\quad y_{i+1}=y E x\left(t_{i+1}\right)\)
    Find \(G E=a b s(y-w)\)
    Output \(t, y, w, G E\)
    Stop
```

## Example (2.4)

Using explicit Adams-Bashforth four-step method with step size $h=0.2$, we can approximate the solution of the initial value problem, $y^{\prime}=y-t^{2}+1, \quad 1 \leq t \leq 3, \quad y(0)=4-0.5 \mathrm{e}^{1}$, and then refine the solution by using $h=0.1$,

This initial value problem has the exact solution $y(t)=(t+1)^{2}-0.5 e^{t}$.

We represented the results for this problem in Table (2.6).
At $t=3$, the global error $5.7083601 \mathrm{E}-03$ for $h=0.2$ and $5.0822471 \mathrm{E}-04$ for $h=0.1$. We note that
$\frac{5.0822471 E-04}{5.7083601 E-03}=0.089032 \approx\left(\frac{0.1}{0.2}\right)^{4}=0.0625$
which agrees with the theoretical error estimate for Adams-Bashforth which is equal to $O\left(h^{4}\right)$.

## Table (2.6): Results of Example (2.4) using Adams-Bashforth 4-step

Figure (2.6) compares the curves of exact and approximate solutions of
Example (2.4).

Figure (2.6): Comparing approximate and exact solutions in Example (2.4)

To derive Milne's methods, we let $r=m-1$ in (2.18), so we get
$y\left(t_{i+1}\right)=y\left(t_{i-m+1}\right)+\int_{t_{i-m+1}}^{t_{i+1}} f(t, y) d t$

If the Newton Backward-Difference interpolating polynomial is integrated over $\left[t_{i-m+1}, t_{i+1}\right]$ using $m-1$ points; $\left(t_{i}, y_{i}\right),\left(t_{i-1}, y_{i-1}\right) \ldots$
$\left(t_{i-m+2}, y_{i-m+2}\right)$, then we get $P_{m-2}$ polynomial and (2.19) becomes
$P_{m-2}(t)=\sum_{k=0}^{m-2}(-1)^{k}\binom{-s}{k} \nabla^{k} f\left(t_{i}, y_{i}\right)$
Again, we have $t=t_{i}+s h . \quad$ Therefore, we get $d t=h d s$.
When $t=t_{i+1}, s=1$. In addition, when $t=t_{i-m+1}, s=-m+1$.
From (2.25) and (2.26), we get

$$
w_{i+1}=w_{i-m+1}+h \sum_{k=0}^{m-2}\left[\nabla^{k} f\left(t_{i}, y_{i}\right) \int_{-m+1}^{1}(-1)^{k}\binom{-s}{k} d s\right] .
$$

For $m=4$ we get

$$
w_{i+1}=w_{i-3}+h \sum_{k=0}^{2}\left[\nabla^{k} f\left(t_{i}, y_{i}\right) \int_{-3}^{1}(-1)^{k}\binom{-s}{k} d s\right]
$$

For $k=0, \int_{-3}^{1}(-1)^{0}\binom{-s}{0} d s=\int_{-3}^{1} d s=4$.
We used Program (2.5) to compute $\int_{-3}^{1}(-1)^{k}\binom{-s}{k} d s$ for $k=1, . .4$ and put the results into Table (2.7) together with the coefficient 4 when $k=0$.

Table (2.7): Coefficients of 4-step Milne's method

| $K$ | 0 | 1 | 2 | 3 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\int_{-3}^{1}(-1)^{k}\binom{-s}{k} d s$ | 4 | -4 | $\frac{8}{3}$ | 0 | $\frac{14}{45}$ |

Using the data in Table (2.7), we get

$$
\begin{aligned}
& w_{i+1}=w_{i-3}+h\left[4 f_{i}-4 \nabla f_{i}+\frac{8}{3} \nabla^{2} f_{i}\right], \\
& w_{i+1}=w_{i-3}+\frac{4 h}{3}\left[2 f_{i}-f_{i-1}+2 f_{i-2}\right],
\end{aligned}
$$

which is the 4 -step explicit Milne's method. Since the coefficient vanishes for $k=3$, the local truncation error becomes
$\left|\tau_{i}\right| \leq \frac{14 h^{m+1} M}{45 * m!}, m=4$.
Therefore, $\tau_{i}=O\left(h^{h+1}\right)$ and the method is of $\mathrm{O}\left(h^{h}\right)$.
The following Algorithm (2.4) approximates the solution to the IVP (1.2) using RK4 to produce the starting points for Milne's 4-step method.

## Algorithm (2.4) Milne's 4-step method

| Step 1: | Define $f(t, y), y E x(t)$ |
| :---: | :---: |
| Step 2: | Input endpoints $a, b$; initial condition $\alpha$; step size $h$ |
| Step 3: | Let number of steps $N=(b-a) / h$ |
| Step 4: | Let $t_{1}=a_{\text {; }}$ |
| Step 5: | Let $w_{1}=\alpha$; The vector $w$ contains the approximad solution of $y$ |
| Step 7: | Let $y_{1}=\alpha$; The vector $y$ contains the exact solution of $y$ |
| Step 8: | For $i=1$ to $N$ repeat steps 8-15 |
| Step 9: | $k_{1}=f\left(t_{i}, w_{i}\right)$ |
| Step 10: | $k_{2}=f\left(t_{i}+1 / 2 h, w_{i}+1 / 2 h k_{1}\right)$ |
| Step 11: | $k_{3}=f\left(t_{i}+1 / 2 h, w_{i}+1 / 2 h k_{2}\right)$ |
| Step 12: | $k_{4}=f\left(t_{i}+h, w_{i}+h k_{3}\right)$ |
| Step 13: | $w_{i+1}=w_{i}+h / 6\left(k_{1}+2 k_{2}+2 k_{3}+k_{4}\right)$ |
| Step 15: | $t_{i+1}=t_{i}+h$ |
| Step 16: | $y_{i+1}=y E x\left(t_{i+1}\right)$ |
| Step 17: | For $i=4$ to $N$ repeat steps $17-19$ |
| Step 18: |  |
| Step 19: | $w_{i+1}=w_{i-3}+h / 3\left[2 f\left(t_{i}, w_{i}\right)-f\left(t_{i-1}, w_{i-1}\right)+2 f\left(t_{i-2}, w_{i-2}\right)\right]$ |
| Step 20: | $t_{i+1}=t_{i}+h$ |
| Step 21: | $y_{i+1}=y E x\left(t_{i+1}\right)$ |

Step 22: Find $G E=a b s(y-w)$
Output $t, y, w, G E$
Stop

We translated this algorithm into the Matlab Program (2.6).

## Example (2.5)

Consider Milne's 4-step method to approximate the solution to the initial value problem
$y^{\prime}(t)=-2 t y, \quad 0 \leq t \leq 1, \quad y(0)=0.5$,
using step size $h=0.1$.
This initial value problem has the exact solution
$y(t)=0.5 e^{-t^{2}}$.
Table (2.8) contains the results of Example (2.5).
Table (2.8): Results of Example (2.5)

| $t_{\mathrm{i}}$ | $y_{\mathrm{i}}$ | $w_{\mathrm{i}}$ | $\left\|G E_{\mathrm{i}}\right\|$ |
| :---: | :---: | :---: | :---: |

### 2.3.2 Implicit Methods

If we use the point $\left(t_{i+1}, f\left(t_{i+1}, y\left(t_{i+1}\right)\right)\right)$ together with the $m$ points used in Adams-Bashforth methods to interpolate $f(t, y)$ in the integral $\int_{t_{i}}^{t_{i+1}} f(t, y) d t$, then we will get an interpolating polynomial $P_{m}$ of degree $m$.

Now, for $t=t_{i}+s h, d t=h . d s$ and $t=t_{i+1}-h+s h=t_{i+1}+(s-1) h$. Therefore, $\binom{-s}{k}$ becomes $\binom{-(s-1)}{k}=\binom{-s+1}{k}$. In addition, for $t=t_{i}, s=0$ and for $t=t_{i+1}, s=1$.

Applying this to (2.22) and (2.23), we get the implicit Adams-Moulton methods
$w_{i+1}=w_{i}+h \sum_{k=0}^{m}\left[\nabla^{k} f\left(t_{i+1}, w_{i+1}\right) \int_{0}^{1}(-1)^{k}\binom{-s+1}{k} d s\right]$.

$$
\left|\tau_{i}\right|<\frac{M h^{m+2}}{(m+1)!} \int_{0}^{1}(s-1) s(s+1) \ldots(s+m-1) d s
$$

Now for $\mathrm{k}=0, \int_{0}^{1}(-1)^{0}\binom{-s+1}{0} \mathrm{ds}=\int_{0}^{1} d s=1$,

$$
\begin{aligned}
& \text { for } \mathrm{k}=1, \int_{0}^{1}(-1)^{1}\binom{-s+1}{1} \mathrm{ds}=\int_{0}^{1}(s-1) d s=-\frac{1}{2}, \\
& \text { for } \mathrm{k}=2, \int_{0}^{1}(-1)^{2}\binom{-s+1}{2} \mathrm{ds}=\frac{1}{2} \int_{0}^{1}(s-1) s d s=-\frac{1}{12}, \\
& \text { for } \mathrm{k}=3, \int_{0}^{1}(-1)^{3}\binom{-s+1}{3} \mathrm{ds}=\frac{1}{3!} \int_{0}^{1}(s-1) s(s+1) d s=-\frac{1}{24}, \\
& \text { for } \mathrm{k}=4, \int_{0}^{1}(-1)^{4}\binom{-s+1}{4} \mathrm{ds}=\frac{1}{4!} \int_{0}^{1}(s-1) s(s+1)(s+2) d s=-\frac{19}{720} .
\end{aligned}
$$

Hence, we have

$$
w_{i+1}=w_{i}+h\left[f_{i+1}-\frac{1}{2} \nabla f_{i}-\frac{1}{12} \nabla^{2} f_{i+1}-\frac{1}{24} \nabla^{3} f_{i+1}-\frac{19}{720} \nabla^{4} f_{i+1}+\cdots\right]
$$

Table (2.9) contains the coefficients $\int_{0}^{1}(-1)^{k}\binom{-s+1}{k} d s$ for $k=0, . .10$. We computed these coefficients using Program (2.7).

Table (2.9): Coefficients of Adams-Moulton methods

| $\mathbf{k}$ | $\int_{0}^{\mathbf{1}}(-\mathbf{1})^{\boldsymbol{k}}\binom{-\boldsymbol{s + 1}}{\boldsymbol{k}} d \boldsymbol{d s}$ |
| :---: | :--- |
| 0 | 1 |
| 1 | $-1 / 2$ |
| 2 | $-1 / 12$ |
| 3 | $-1 / 24$ |
| 4 | $-19 / 720$ |
| 5 | $-3 / 160$ |
| 6 | $-863 / 60480$ |
| 7 | $-275 / 24192$ |
| 8 | $-33953 / 3628800$ |
| 9 | $-8183 / 1036800$ |
| 10 | $-3250433 / 479001600$ |

Now, for $m=0$, we get
$w_{i+1}=w_{i}+h f\left(t_{i+1}, w_{i+1}\right)$,
which is the backward Euler's method of order 2.
For $\mathrm{m}=1$, we get the 1 -step method of order 2

$$
\begin{aligned}
w_{i+1} & =w_{i}+h\left[f_{i+1}-\frac{1}{2} \nabla f_{i+1}\right] \\
=w_{i}+ & h\left[f_{i+1}-\frac{1}{2}\left(f_{i+1}-f_{i}\right)\right] \\
& =w_{i}+\frac{h}{2}\left[f_{i+1}+f_{i}\right] .
\end{aligned}
$$

For $m=2$, we get the 2 -step method of order 3

$$
w_{i+1}=w_{i}+\frac{h}{12}\left[5 f_{i+1}+8 f_{i}-f_{i-1}\right] .
$$

For $m=3$, we get the 3 -step method of order 4 and $\tau_{i}=O\left(h^{4}\right)$.

$$
\begin{equation*}
w_{i+1}=w_{i}+\frac{h}{24}\left[9 f_{i+1}+19 f_{i}-5 f_{i-1}+f_{i-2}\right] . \tag{2.28}
\end{equation*}
$$

## Example (2.6)

We can approximate the solution to the initial value problem in Example (2.4), using the 3-step fourth order Adams-Moulton method with step size $h=0.2$, and compare the results with the results we got in Example (2.4) for the same step size.

At first, we must solve (2.28) algebraically for $w_{i+1}$, where
$f\left(t_{i+1}, w_{i+1}\right)=w_{i+1}-\left(t_{i+1}\right)^{2}+1$
Doing that, we get

$$
w_{i+1}=\frac{24}{24-9 h}\left[w_{i}+\frac{h}{24}\left[9\left(-t_{i+1}^{2}+1\right)+19 f_{i}-5 f_{i-1}+f_{i-2}\right]\right] .
$$

Then we insert this explicit formula as a 3-step Adams-Moulton method in Program (2.7), which gives the results illustrated in Table (2.10).

Table (2.10): Results using the 3-step Adams-Moulton method for Example (2.6)

| $t_{i}$ | $y_{i}$ | $w_{i}$ | $G E_{i}$ |
| :---: | :---: | :---: | :---: |
| 1.0000000 | 2.6408591 | 2.6408591 | $0.0000000 \mathrm{E}+00$ |
| 1.2000000 | 3.1799417 | 3.1799386 | $2.9179384 \mathrm{E}-06$ |
| 1.4000000 | 3.7323999 | 3.7323945 | $5.6519293 \mathrm{E}-06$ |
| 1.6000000 | 4.2834840 | 4.2834592 | $2.4484483 \mathrm{E}-05$ |
| 1.8000000 | 4.8151765 | 4.8151245 | $5.1853749 \mathrm{E}-05$ |
| 2.0000000 | 5.3054719 | 5.3053818 | $9.0046029 \mathrm{E}-05$ |
| 2.2000000 | 5.7274933 | 5.7273507 | $1.4260200 \mathrm{E}-04$ |
| 2.4000001 | 6.0484118 | 6.0481977 | $2.1401687 \mathrm{E}-04$ |
| 2.5999999 | 6.2281308 | 6.2278209 | $3.1006479 \mathrm{E}-04$ |
| 2.8000000 | 6.2176766 | 6.2172384 | $4.3815278 \mathrm{E}-04$ |
| 3.0000000 | 5.9572315 | 5.9566236 | $6.0776027 \mathrm{E}-04$ |

The global error at $t=3$ using Adams-Moulton method is $6.0776027 \mathrm{E}-04$, while it was $5.7083601 \mathrm{E}-03$ in Example (3.1). This means that we have about 9.4 times less error in the 3 -step Adams-Moulton method than the error produced by the 4 -step Adams-Bashforth method. Although implicit AdamsMoulton methods give better results than the explicit Adams-Bashforth methods of the same order, they have the weakness of that we have to convert them algebraically to an explicit representation for $w_{i+1}$.

Figure (2.8): Comparing approximate and exact solutions of Example (2.6)
Figure (2.8) compares the approximate and exact solutions of Example (2.6).

### 2.3.3 Predictor-Corrector Methods

Since implicit multistep methods must be solved algebraically for $w_{i+1}$ before using them to approximate the solution, they are usually not used alone. Rather, they are used with explicit methods to improve the results. Because implicit methods need the value of $w_{i+1}$ at $t_{i+1}$, explicit methods are used to approximate $w_{i+1}$ for them. This technique of approximating $w_{i+1}$ by explicit methods and improve approximations by implicit methods is called predictorcorrector methods.

As an example, we will use Adams-Bashforth 4th-order 4-step method
$w_{i+1}=w_{i}+\frac{h}{24}\left[55 f_{i}-59 f_{i-1}+37 f_{i-2}-9 f_{i-3}\right]$
as a predictor method and Adams-Moulton 4th-order 3-step method

$$
w_{i+1}=w_{i}+\frac{h}{24}\left[9 f_{i+1}+19 f_{i}-5 f_{i-1}+f_{i-2}\right]
$$

as a corrector method for solving an initial value problem. We first need to calculate the starting values $w_{1}, w_{2}, w_{3}, w_{4}$ for the explicit Adams-Bashforth 4-Step method. To do this, we will use the 4th-order 1-step Runge-Kutta method.

## Example (2.7)

Consider using the 4 -step Adams-Bashforth method as a predictor and the 3step Adams-Moulton method as a corrector to approximate the solution to the initial-value problem in Example (2.4) with $h=0.2$. We consider using the fourth order Runge-Kutta method to approximate the starting values.

## Table (2.11): Results of Example (2.7)

| $t_{i}$ | $y_{i}$ | $w_{i}$ | $G E_{i}$ |
| :---: | :---: | :---: | :---: |
| 1.0000000 | 2.6408591 | 2.6408591 | $0.0000000 \mathrm{E}+00$ |
| 1.2000000 | 3.1799417 | 3.1799386 | $2.9179384 \mathrm{E}-06$ |
| 1.4000000 | 3.7323999 | 3.7323945 | $5.6519293 \mathrm{E}-06$ |
| 1.6000000 | 4.2834840 | 4.2834759 | $7.9774882 \mathrm{E}-06$ |
| 1.8000000 | 4.8151765 | 4.8151636 | $1.2691397 \mathrm{E}-05$ |
| 2.0000000 | 5.3054719 | 5.3054528 | $1.9202997 \mathrm{E}-05$ |
| 2.2000000 | 5.7274933 | 5.7274652 | $2.7937787 \mathrm{E}-05$ |
| 2.4000001 | 6.0484118 | 6.0483723 | $3.9602623 \mathrm{E}-05$ |
| 2.5999999 | 6.2281308 | 6.2280760 | $5.5064698 \mathrm{E}-05$ |
| 2.8000000 | 6.2176766 | 6.2176013 | $7.5431999 \mathrm{E}-05$ |
| 3.0000000 | 5.9572315 | 5.9571295 | $1.0211881 \mathrm{E}-04$ |

For the predictor-corrector method the global error at $t=3$ is $1.0211881 \mathrm{E}-$ 04 which is about six times less than the error ( $6.0776027 \mathrm{E}-04$ ) generated by the implicit Adams-Moulton method and about 56 times less than the error (5.7083601E-03) generated by Adams-Bashforth method. Both the AdamsBashforth and the predictor-corrector methods took advantage at $t=1.6$ by
the higher accuracy of Runge-Kutta, but this is not the case for Moulton's method.

### 2.4 Stability and Stability Regions [8, 12]

In this section, we will study absolute stability of one-step numerical schemes. Absolute stability considers the behavior of the numerical scheme when the time step $h$ is held fixed and $t \rightarrow \infty$.

A numerical method is stable if and only if it is consistent and stable. Moreover, if a numerical is stable and has local truncation error equals to $O\left(h^{p+1}\right)$ then it has global error equals to $O\left(h^{p}\right)$.

This means that if a method is consistent and stable then $\left|y\left(t_{i}\right)-w_{i}\right| \rightarrow 0$ as $t_{i} \rightarrow \infty$. In other words global error vanishes as $t \rightarrow \infty$.

Our model for studying stability will be
$y^{\prime}(t)=\lambda y(t), \quad \mathrm{y}(0)=1, \quad t>0, y(t)=e^{\lambda t}, \lambda \in \mathbb{C}$.
For $z=\alpha h$, the numerical scheme is absolutely stable if [8]
$|G(z)|<1$,
where
$G(z)=\frac{w_{i+1}}{w_{i}}$.

## Definition (2.5) [8]

The locus S of points $\mathrm{z} \in \mathrm{C}$ for which $|G(z)|<1$ is called the (absolute) stability region of the scheme.
Since $z=|z| e^{\theta i}$, the boundary of the region of absolute stability is the roots of the equation

$$
\begin{equation*}
\mathrm{G}(\mathrm{z})=e^{\theta i}, \quad 0 \leq \theta<2 \pi . \tag{2.30}
\end{equation*}
$$

Now, for Euler's forward method
$w_{i+1}=w_{i}+h f\left(t_{i}, w_{i}\right)$
$w_{i+1}=w_{i}+\lambda h w_{i}$
$\frac{w_{i+1}}{w_{i}}=1+\lambda h$
$G(z)=1+z$.
We wrote a Matlab Program (2.9) to find the roots of (2.30) at equally spaced values in the interval $[0,2 \pi[$ and to plot these roots.

To find the boundary of the region of absolute stability for Euler's forward method, we run Program (2.9) for $G(z)=1+z$.

Figure (2.9) (a) shows the stability region (shaded) for Euler's forward method. In addition, Figure (2.9) (b) shows the stability region (shaded) for Euler's backward method.

Figure (2.9): (a) Stability region for Euler's Forward method
(b) Stability region for Euler's Backward method

We find that the stability region is the inner of the disk (Figure (2.9) (a)) with center ( $-1,0$ ) and radius equals one. This means that $\lambda h$ must be inside this disk. For complex $\lambda=a+b i$, we $(h a+1)^{2}+(h b-0)^{2}<1$

$$
(h a)^{2}+2 h a+1+(h b)^{2}<1 \quad \text { dividing by } \quad h>0
$$

$h a^{2}+2 a+h b^{2}<0$
$h<\frac{-2 a}{a^{2}+b^{2}}$.
This means that for $a>0$, there is no $h$ satisfies (2.31). Therefore, Euler's method is not stable when $\operatorname{real}(\lambda)>0$ and absolutely stable when $\operatorname{real}(\lambda)<0$ and $h$ satisfies (2.31). To make this clearer, we take $\lambda_{1}=1+2 i$ and $\lambda_{2}=-1+2 i$. For $\lambda_{1}$, there is no $\mathrm{h}<\frac{-2}{5}$, meaning that for any choice of $h$, Euler's method is unstable. For $\lambda_{2}$, we must choose $h<\frac{2}{5}=0.4$ so that the method is stable.

We will use the three dimensional Cartesian coordinate system to plot the complex numbers y and was they vary with $t$.

Figure (2.10): Relation between $\lambda, h$ and stability of Euler's method:
(a) $\mathrm{t}=200 \mathrm{~h}=0.001, \lambda_{1}=1+2 i$
(b) $\mathbf{t}=200, \mathrm{~h}=0.1, \lambda_{2}=-1+2 i$
(c) $\mathrm{t}=200, \mathrm{~h}=0.5, \lambda_{2}=-1+2 i$

Figure (2.10) (a) shows that Euler's method is unstable for $\lambda_{1}=1+2 i$, even though we chose $h=0.001$. Figure (2.10) (b) shows that Euler's method is stable for $\lambda_{2}=-1+2 i$ and $h=0.1<0.4$. But, Figure (2.10) (c) shows that Euler's method is unstable for $\lambda_{2}=-1+2 i$ and $h=0.5>0.4$.

To study stability of backward Euler's method, we have
$w_{i+1}=w_{i}+h f\left(t_{i+1}, w_{i+1}\right)$
$w_{i+1}=w_{i}+h \lambda w_{i+1}$
$w_{i+1}-h \lambda w_{i+1}=w_{i}$
$\frac{w_{i+1}}{w_{i}}=\frac{1}{1-\lambda h}$
$G(z)=\frac{1}{1-z}$.
We used Program (2.10) to plot the boundary of the region of absolute stability for $G(z)=\frac{1}{1-z}$. Figure (2.9) (b) shows the stability region for this method is the outer side of the disk with centre $(1,0)$ and radius 1 .

We can find the function $G$ for other methods in the same way as we did for Euler's methods.

We wrote Program (2.11) to find $G(z)$ for explicit RK methods and to plot the boundary of regions of stability. Table (2.12) contains $G(z)$ for RK methods $1, \ldots, 4$, generated by Program (2.11). Figure (2.11) contains the regions of stability of RK methods $1,2,3$ and 4 , generated by Program (2.11).

## Table (2.12): Amplification functions G(z) for RK1,...,RK4

| Method | G(z) |
| :--- | :--- |

| RK1 | $1+z$ |
| :--- | :--- |
| RK2 | $1+z+1 / 2^{*} z^{\wedge} 2$ |
| RK3 | $1+z+1 / 2^{*} z^{\wedge} 2+1 / 6^{*} z^{\wedge} 3$ |
| RK4 | $1+z+1 / 2^{*} z^{\wedge} 2+1 / 6^{*} z^{\wedge} 3+1 / 24^{*} z^{\wedge} 4$ |

Figure (2.11): Stability regions for RK1,...,RK4

Finally, we will derive the functions $G(z)$ for Taylor methods. First, we note that

$$
y^{\prime}=\lambda y, \quad y^{\prime \prime}=\lambda^{2} y, \ldots, \quad y^{(n)}=\lambda^{n} y
$$

Therefore, Taylor's method of order n will be
$w_{i+1}=w_{i}+h \lambda w_{i}+\frac{h^{2} \lambda^{2}}{2} w_{i}+\cdots+\frac{(h \lambda)^{n}}{n!} w_{i}$
$w_{i+1}=w_{i}+z w_{i}+\frac{z^{2}}{2} w_{i}+\cdots+\frac{z^{n}}{n!} w_{i}$
And hence,
$G(z)=1+z+\cdots+\frac{z^{n}}{n!}=\sum_{p=1}^{n} \frac{z^{p}}{p!}$.

Program (2.12) is designed to plot the boundary of the regions of stability of any range of Taylor's methods. We used this program to plot these boundaries for Taylor's methods $n=1, \ldots, 6$ in Figure (2.12).

Figure (2.12): Stability regions for Taylor1,..., Taylor6 methods
Figure (2.13) demonstrates stability behavior of fourth order Taylor's method when applied to (2.29) with different values of h and lambda. The method shows absolute stability in (b), (d) and (g). It shows instability in (a), (c) and (f). In (e) the error remains bounded and the method is stable but not absolutely stable.

Figure (2.13): Stability behavior of fourth order Taylor method:
(a) lambda=10+1*i; h=.1; b=5

Figure (2.13) :(b) lambda=-2+1*i; $h=.1 ; b=5$

Figure (2.13): (c) lambda=-50+1*i; $\mathrm{h}=.1$; $\mathrm{b}=5$;

Figure (2.13) :(d) lambda=1*i; $h=.1 ; b=30$

Figure (2.13): (e) lambda=10*i; $h=.1 ; b=100$;

Figure (2.13): (f) lambda $=-40 * i ; h=.1 ; b=100$;

Figure (2.13) (g) lambda=-i; $\mathbf{h = . 1 ;} \mathbf{b = 1 0 0 ;}$

## Chapter Three <br> Higher Order Taylor Methods

### 3.1 Introduction

In this chapter, we will be focusing on solving first order initial value problems, systems of first order initial value problems and higher order initial value problems, using higher order Taylor methods. Here, a question arises, since Taylor methods are well known, why we have chosen to investigate Taylor methods. Taylor methods have the weakness of having to find higher order derivatives needed to construct these methods. We thought, it is worth to develop an algorithm and later a computer program to accomplish this task. In this chapter and in the next chapter we will try to answer this question.

### 3.2 Higher Order Taylor Methods for Solving First Order IVP

In this section, we will develop some numerical algorithms to find $y^{\prime \prime}(t), \ldots$, $y^{(n)}(\mathrm{t})$ of our basic problem,
$y^{\prime}(t)=f(t, y), \quad a \leq t \leq b, \quad y(a)=\alpha$
and construct nth order Taylor methods to solve this problem.

### 3.2.1 Finding Higher Order Derivatives of First Order IVP's

## Theorem (3.1) [17]

If $w$ is a function of $u_{1}, u_{2}, \ldots, u_{k}$ and each is a function of one variable $t$, then $w$ is a function of $t$ and

$$
\frac{d w}{d t}=\frac{\partial w}{\partial u_{1}} \frac{d u_{1}}{d t}+\frac{\partial w}{\partial u_{2}} \frac{d u_{2}}{d t}+\ldots+\frac{\partial w}{\partial u_{k}} \frac{d u_{k}}{d t} .
$$

Applying this theorem on

$$
y^{\prime}(\mathrm{t})=f(\mathrm{t}, \mathrm{y}(\mathrm{t})),
$$

where $f, t$ and $y$ represent $w, u_{1}$ and $u_{2}$ in the theorem respectively, we get

$$
\frac{d y^{\prime}}{d t}=\frac{\partial f}{\partial t} \frac{d t}{d t}+\frac{\partial f}{\partial y} \frac{d y}{d t} .
$$

That is

$$
y^{\prime \prime}=\frac{\partial y^{\prime}}{\partial t}+\frac{\partial y^{\prime}}{\partial y} y^{\prime}
$$

Now let

$$
h(t, y)=y^{\prime \prime}(t) .
$$

Applying theorem (3.1) on $h$ we get

$$
\begin{aligned}
& \frac{d y^{\prime \prime}}{d t}=\frac{\partial h}{\partial t} \frac{d t}{d t}+\frac{\partial h}{\partial y} \frac{d y}{d t}, \\
& y^{\prime \prime \prime}=\frac{\partial y^{\prime \prime}}{\partial t}+\frac{\partial y^{\prime \prime}}{\partial y} y^{\prime} .
\end{aligned}
$$

Repeating this process until we get

$$
\begin{equation*}
y^{(n)}=\frac{\partial y^{(n-1)}}{\partial t}+\frac{\partial y^{(n-1)}}{\partial y} y^{\prime} . \tag{3.1}
\end{equation*}
$$

From (3.1), we get an iterative method to find higher order derivatives $y^{\prime \prime}$, $y^{\prime \prime \prime}, \ldots, y^{(n)}$ of first order IVP's and that is:

$$
\begin{equation*}
y^{(i)}=\frac{\partial y^{(i-1)}}{\partial t}+\frac{\partial y^{(i-1)}}{\partial y} y^{\prime}, i=2,3, \ldots, n . \tag{3.2}
\end{equation*}
$$

Algorithm (3.1) finds $y^{\prime \prime}, y^{\prime \prime \prime}, \ldots, y^{(n)}$ and store them together with $y^{\prime}$ in the vector $y_{p}$, where $y_{p}(i)=y^{(i)}$. We translated Algorithm (3.1) into a Matlab Program (3.1), which we will use to find the derivatives.

## Algorithm (3.1) Finds the first $n$ derivatives of $y(t)$ where $y^{\prime}(t)=f(t, y)$

To find the first $n$ derivatives of $y(t)$ where $y^{\prime}(t)=f(t, y)$.
We wil use the vector $y_{p}$ to hold the derivatives.
Step 1: Define t,y as symbols
Step 2: Define $f(t, y)$
Step 3: Input $n$
Step 4: $\quad$ Let $y^{(1)}=f(t, y)$
Step 5: Let $y_{p}(1)=y^{(1)}$
Step 6: For $i=2$ to $n$ repeat step $7-8$
Step 7: $\quad$ Let $y^{(i)}=\frac{\partial y^{(i-1)}}{\partial t}+\frac{\partial y^{(i-1)}}{\partial y} * y^{(1)}$
Step 8: $\quad$ Let $y_{p}(i)=y^{(i)}$
Step 9: Output $y_{p}$
Step10: Stop

## Example (3.1)

We can find the first 4 derivatives of $y(t)$ where $y^{I}(t)=\exp (y)$.
Running Program (3.1) for $y^{\prime}(t)=\exp (\mathrm{y})$ and $\mathrm{n}=4$, produces the vector $y_{p}$, where

$$
y_{p}=[\exp (y), \exp (2 * y), 2 * \exp (3 * y), 6 * \exp (4 * y)]
$$

That is

$$
y^{\prime}=\exp (y), y^{\prime \prime}=\exp \left(2^{*} y\right), y^{\prime \prime \prime}=2^{*} \exp \left(3^{*} y\right) \text { and } y^{(4)}=6^{*} \exp \left(4^{*} y\right)
$$

## Example (3.2)

Consider running Program (3.1) for $y^{\prime}=y \exp (y)$ and $n=20$.

Doing that, we get $y_{p}$ where

$$
\begin{aligned}
& \mathrm{y}_{\mathrm{p}} 1=\mathrm{y}^{*} \exp (\mathrm{y}) \\
& y_{p} 2=\exp \left(2^{*} y\right)^{*}(1+y)^{*} y \\
& y_{\mathrm{p}} 3=\exp \left(3^{*} \mathrm{y}\right)^{*}\left(4^{*} \mathrm{y}+2^{*} \mathrm{y}^{\wedge} 2+1\right)^{*} \mathrm{y} \\
& y_{\mathrm{p}} 4=\exp \left(4^{*} \mathrm{y}\right)^{*}\left(18^{*} \mathrm{y}^{\wedge} 2+6^{*} \mathrm{y}^{\wedge} 3+11^{*} \mathrm{y}+1\right)^{*} \mathrm{y} \\
& y_{\mathrm{p}} 5=\exp \left(5^{*} \mathrm{y}\right)^{*}\left(96^{*} \mathrm{y}^{\wedge} 3+24^{*} \mathrm{y}^{\wedge} 4+98^{*} \mathrm{y}^{\wedge} 2+26^{*} \mathrm{y}+1\right)^{*} \mathrm{y} \\
& \mathrm{y}_{\mathrm{p}} 6=\exp \left(6^{*} \mathrm{y}\right)^{*}\left(600^{*} \mathrm{y}^{\wedge} 4+120^{*} \mathrm{y}^{\wedge} 5+874^{*} \mathrm{y}^{\wedge} 3+424^{*} \mathrm{y}^{\wedge} 2+57^{*} \mathrm{y}+1\right)^{*} \mathrm{y} \\
& \mathrm{y}_{\mathrm{p}} 7=\exp \left(7^{*} \mathrm{y}\right)^{*}\left(4320^{*} \mathrm{y}^{\wedge} 5+720^{*} \mathrm{y}^{\wedge} 6+8244^{*} \mathrm{y}^{\wedge} 4+6040^{*} \mathrm{y}^{\wedge} 3+1614^{*} \mathrm{y}^{\wedge} 2\right. \\
& \left.+120^{*} \mathrm{y}+1\right)^{*} \mathrm{y} \\
& \mathrm{yp}_{\mathrm{p}} 8=\exp \left(8^{*} \mathrm{y}\right)^{*}\left(35280^{*} \mathrm{y}^{\wedge} 6+5040^{*} \mathrm{y}^{\wedge} 7+83628^{*} \mathrm{y}^{\wedge} 5+83500^{*} \mathrm{y}^{\wedge} 4\right. \\
& \left.+35458^{*} \mathrm{y}^{\wedge} 3+5682^{*} \mathrm{y}^{\wedge} 2+247^{*} \mathrm{y}+1\right)^{*} \mathrm{y} \\
& y_{p} 9=\exp \left(9^{*} y\right)^{*}\left(322560^{*} y^{\wedge} 7+40320^{*} y^{\wedge} 8+915984^{*} y^{\wedge} 6+1169768\right. \\
& \left.{ }^{*} y^{\wedge} 5+701164^{*} y^{\wedge} 4+187288^{*} y^{\wedge} 3+19022^{*} y^{\wedge} 2+502^{*} y+1\right)^{*} y \\
& y_{p} 10=\exp \left(10^{*} y\right)^{*}\left(1+61584^{*} \mathrm{y}^{\wedge} 2+920350^{*} \mathrm{y}^{\wedge} 3+5191412^{*} \mathrm{y}^{\wedge} 4\right. \\
& +13329084^{*} y^{\wedge} 5+1013^{*} \mathrm{y}+16939800^{*} \mathrm{y}^{\wedge} 6+10824336^{*} \mathrm{y}^{\wedge} 7 \\
& \left.+3265920^{*} y^{\wedge} 8+362880^{*} y^{\wedge} 9\right)^{*} y \\
& \mathrm{y}_{\mathrm{p}} 11=\exp \left(11^{*} \mathrm{y}\right)^{*}\left(1+194882^{*} \mathrm{y}^{\wedge} 2+4297240^{*} \mathrm{y}^{\wedge} 3+35160560^{*} \mathrm{y}^{\wedge} 4\right. \\
& +131888624{ }^{*} y^{\wedge} 5+2036 * y+251869440^{*} y^{\wedge} 6+255992688^{*} y^{\wedge} 7 \\
& \left.+137636640^{*} y^{\wedge} 8+36288000^{*} y^{\wedge} 9+3628800^{*} y^{\wedge} 10\right)^{*} \mathrm{y} \\

### 3.2.2 Constructing Taylor Expansion for First order IVP's

The next Algorithm (3.1) finds the first n derivatives of $y(t)$, where $y^{\prime}(t)=f(t, y)$ and constructs the nth order $T^{(n)}\left(t_{i}, y_{i}, h\right)$ defined in (2.8) $T^{(n)}\left(t_{i}, y_{i}, h\right)=\left[y_{i}^{\prime}+\frac{1}{2} h y_{i}^{\prime \prime}+\cdots+\frac{1}{n!} h^{n-1} y_{i}^{(n)}\right]$,
for the nth order Taylor method (2.16)
$w_{i+1}=w_{i}+h T^{(n)}\left(t_{i}, w_{i}, h\right), \quad \mathrm{i}=1, \ldots, \mathrm{~N}$.
We translated this algorithm into a Matlab Program (3.2), which we will use to solve the following examples.
Algorithm (3.2) Finds the first $n$ derivatives of $y(t)$ where $y^{\prime}(t)=f(t, y)$ and constructs $T$
To construct $T$ defined as $T^{(n)}$ in $(2.8)$ by finding first the derivatives of $y(t)$
where $y^{\prime}(t)=f(t, y)$
We wil use the vector $y_{p}$ to hold the derivatives.
Step 1: Define $t, y$ and $h$ as sympols
Step 2: Define $f(t, y)$
Step 3: $\quad$ Input $n$
Step 4: Let $f a c=1$
Step 5: Let $y^{(1)}=f(t, y)$
Step 6: Let $T=y^{(1)}$
Step 7: Let $y_{p}(1)=y^{(1)}$
Step 8: For $i=2$ to $n$ repeat steps $9-12$

| Step 9: Let $y^{(i)}=\frac{\partial y^{(i-1)}}{\partial \mathrm{t}}+\frac{\partial y^{(i \mathrm{i}-1)}}{\partial y} * y^{(1)}$ <br> Step 10: Let $f a c=f a c * i$ <br> Step 11: Let $T=T+\frac{h^{i-1}}{f a c} * y^{(i)}$ <br> Step 12: Let $y p(i)=y^{(i)}$ <br> Step 13: Output $y_{p,}, T$ <br> Step 14: Stop  |
| :--- | :--- |

## Example (3.3)

Consider constructing $T^{(4)}$ for $y^{\prime}(t)$, where $y^{\prime}(t)=\log (t)$.
Entering $n=4$ and $y^{\prime}(t)=\log (t)$ into Program (3.2), we get

$$
T^{(4)}=\log (t)+1 / 2 * h / t-1 / 6 * h^{\wedge} 2 / t^{\wedge} 2+1 / 12 * h^{\wedge} 3 / t^{\wedge} 3 .
$$

## Example (3.4)

Consider running Program (3.2) for $n=15$ and $y^{\prime}=t-y$.
Doing that, we get

$$
\begin{aligned}
& T^{(15)}=\mathrm{t}-\mathrm{y}+1 / 2 * \mathrm{~h}^{*}(1-\mathrm{t}+\mathrm{y})+1 / 6 * \mathrm{~h}^{\wedge} 2 *(-1+\mathrm{t}-\mathrm{y})+1 / 24 * \mathrm{~h}^{\wedge} 3 *(1-\mathrm{t}+\mathrm{y})+1 / 120^{*} \mathrm{~h}^{\wedge} 4 \\
& \quad *(-1+\mathrm{t}-\mathrm{y})+1 / 720 * \mathrm{~h}^{\wedge} 5^{*}(1-\mathrm{t}+\mathrm{y})+1 / 5040 * \mathrm{~h}^{\wedge} 6 *(-1+\mathrm{t}-\mathrm{y})+1 / 40320 * \mathrm{~h}^{\wedge} 7 *(1-\mathrm{t}+\mathrm{y}) \\
& \quad+1 / 362880 * \mathrm{~h}^{\wedge} 8 *(-1+\mathrm{t}-\mathrm{y})+1 / 3628800 * \mathrm{~h}^{\wedge} 9^{*}(1-\mathrm{t}+\mathrm{y})+1 / 39916800 * \mathrm{~h}^{\wedge} 10 \\
& \quad *(-1+\mathrm{t}-\mathrm{y})+1 / 479001600 * \mathrm{~h}^{\wedge} 11 *(1-\mathrm{t}+\mathrm{y})+1 / 6227020800 * \mathrm{~h}^{\wedge} 12 *(-1+\mathrm{t}-\mathrm{y}) \\
& \quad+1 / 87178291200 * \mathrm{~h}^{\wedge} 13 *(1-\mathrm{t}+\mathrm{y})+1 / 1307674368000 * \mathrm{~h}^{\wedge} 14 *(-1+\mathrm{t}-\mathrm{y}) .
\end{aligned}
$$

### 3.2.3 Approximating the Solution of First Order IVP's using Higher

## Order Taylor Methods

Now, we are ready to introduce an algorithm to approximate the solution of the first order initial value problem using higher order Taylor methods.

Algorithm (3.3) enables the user to approximate IVPs with different Taylor orders ( $n$ ) and step sizes ( $h$ ). It also, finds numerical approximations and exact values of the solution of the problem at each $t_{i}$ and stores them in the vectors $w$ and $y$. In addition, it finds the accumulated global errors at each step and stores them in the vector named 'error'.

We translated Algorithm (3.3) into Matlab Program (3.3) to find $T^{(n)}$, generates nth Taylor's higher order method and uses it to approximate the solution of the first order IVP.

## Algorithm (3.3) Solves first order IVPs using higher order Taylor methods and compares with the exact solution

To approximate the solution of the IVP $y^{\prime}(t)=f(t, y), a \leq t \leq b, y(a)=\alpha$ And compare the approximated solution $w$ with the exact solution $y$ We will use T constructed by algorithm (3.2)

Step 1: Define $f(t, y)$; and $y E x(t)$
Step 2: Input endpoints $a, b$ initial condition $y(a)=\alpha$
Step 3: Input Taylors ordern; stepsize $h$
Step 4: Let $N=(b-a) / h$
Step 5: Let $t(1)=a ; w(1)=\alpha ; y E x a c t(1)=\alpha$
Step 6: Let $y^{\prime}(t)=f(t, y)$
Step 7: Use algorithm (3.2) to Get $T$
Step 8: For $i=1$ to $N$ repeat steps 9-11
Step 9: $\quad w(i+1)=w(i)+h * T(t(i), w(i), h)$
Step 10: $\quad y(i+1)=y E x(t(i+1))$
Step 11: $\quad t(i+1)=t(i)+h$
Step 12: $\quad G E=a b s(y-w)$

Step 13: Output $t, y, w, G E$
Step 14: Stop

## Example (3.5)

We can find numerical approximation of the solution of the next IVP, using step size $h=0.1$ and Taylor methods of orders $n=4$ and $n=10$.
$\mathrm{y}^{\prime}(\mathrm{t})=\frac{(2-2 \mathrm{ty})}{t^{2}+1}, \quad 0 \leq \mathrm{t} \leq 1, \quad \mathrm{y}(0)=1$.
The exact solution of this problem is
$\mathrm{y}(\mathrm{t})=\frac{(2 \mathrm{t}+1)}{t^{2}+1}$.
The results of running Program (3.3) for $h=0.1$ and $n=4,10$ are represented in Table (3.1) and Figure (3.1).

The generated Taylor iterative method for $\mathrm{n}=4$ and $\mathrm{h}=0.1$ is

$$
w_{i+1}=w_{i}+h T^{(4)}\left(t_{i}, w_{i}\right) ; \mathrm{h} \text { is replaced by its value } 0.1,
$$

where

$$
\begin{aligned}
T^{(4)}(t, y) & =\left(2-2 * t^{*} \mathrm{y}\right) /\left(\mathrm{t}^{\wedge} 2+1\right)+1 / 10^{*}\left(3 * \mathrm{y}^{*} \mathrm{t}^{\wedge} 2-\mathrm{y}-4 * \mathrm{t}\right) /\left(\mathrm{t}^{\wedge} 2+1\right)^{\wedge} 2 \\
& -1 / 50^{*}\left(2 * \mathrm{t}^{\wedge} 3 * \mathrm{y}-2 * \mathrm{t}^{*} \mathrm{y}-3 * \mathrm{t}^{\wedge} 2+1\right) /\left(\mathrm{t}^{\wedge} 2+1\right)^{\wedge} 3+1 / 1000 \\
& *\left(5 * \mathrm{y}^{*} \mathrm{t}^{\wedge} 4-10 * \mathrm{y}^{*} \mathrm{t}^{\wedge} 2+\mathrm{y}-8 * \mathrm{t}^{\wedge} 3+8 * \mathrm{t}\right) /\left(\mathrm{t}^{\wedge} 2+1\right)^{\wedge} 4
\end{aligned}
$$

The generated Taylor iterative method for $n=10$ and $h=0.1$ is

$$
w_{i+1}=w_{i}+h T^{(10)}\left(t_{i}, w_{i}\right) ; \mathrm{h} \text { is replaced by its value } 0.1,
$$

where

$$
T^{(10)}(\mathrm{t}, \mathrm{y})=\left(2-2 * \mathrm{t}^{*} \mathrm{y}\right) /\left(\mathrm{t}^{\wedge} 2+1\right)+1 / 10 *\left(3 * \mathrm{y}^{*} \mathrm{t}^{\wedge} 2-\mathrm{y}-4 * \mathrm{t}\right) /\left(\mathrm{t}^{\wedge} 2+1\right)^{\wedge} 2
$$

Figure (3.1) compares the exact solution y and the approximated solution of the IVP in Example (3.5) using fourth order Taylor method with step size $h=0.1$. It shows how close the approximated and exact solutions are.

Figure (3.1): Comparing approximated solution w by fourth order Taylor method and exact solution $y$ of the IVP in Example (3.5) with $\mathrm{h}=0.1$

### 3.3 Higher Order Taylor Methods for Systems of First Order IVP's

A system consisting of k equations of first order ordinary differential equations can be written as

$$
\begin{align*}
& u_{1}^{\prime}(\mathrm{t})=f_{1}\left(\mathrm{t}, \mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{k}}\right), \\
& u_{2}^{\prime}(\mathrm{t})=f_{2}\left(\mathrm{t}, \mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{k}}\right), \\
& \vdots
\end{align*}
$$

where $u_{1}, \ldots, u_{k}$ are functions of $t$.
Reformulating (3.3), we get

$$
\begin{equation*}
u_{j}^{I}(\mathrm{t})=f_{\mathrm{j}}\left(\mathrm{t}, \mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{k}}\right), \quad \mathrm{j}=1,2, \ldots, \mathrm{k} . \tag{3.4}
\end{equation*}
$$

Now, applying theorem (3.1) to each equation in (3.4), where $j=1,2, \ldots, k$, we get

$$
\begin{equation*}
u_{j}^{\prime \prime}(\mathrm{t})=\frac{\partial f_{j}}{\partial t} \frac{d t}{d t}+\frac{\partial f_{j}}{\partial u_{1}} \frac{d u_{1}}{d t}+\frac{\partial f_{j}}{\partial u_{2}} \frac{d u_{2}}{d t}+\ldots+\frac{\partial f_{j}}{\partial u_{k}} \frac{d u_{k}}{d t} . \tag{3.5}
\end{equation*}
$$

Substituting $f_{\mathrm{j}}$ by $u_{i}^{\prime}$, (3.3) becomes

$$
u_{j}^{\prime \prime}(\mathrm{t})=\frac{\partial u_{j}^{\prime}}{\partial t}+\frac{\partial u_{j}^{\prime}}{\partial u_{1}} u_{1}^{r} \quad \frac{\partial u_{j}^{\prime}}{\partial u_{2}} u_{2}^{r}+\ldots+\frac{\partial u_{j}^{\prime}}{\partial u_{k}} u_{k}^{r} .
$$

Now, letting

$$
g_{j}(\mathrm{t})=u_{j}^{\prime \prime}(\mathrm{t})=\frac{\partial u_{j}^{\prime}}{\partial t}+\frac{\partial u_{j}^{\prime}}{\partial u_{1}} u_{1}^{r} \quad \frac{\partial u_{j}^{\prime}}{\partial u_{2}} u_{2}^{r}+\ldots+\frac{\partial u_{j}^{\prime}}{\partial u_{k}} u_{k}^{\prime}
$$

and applying Theorem (3.1) again to $g_{j}(\mathrm{t})$, then we get

$$
g_{j}^{r}(\mathrm{t})=u_{j}^{w \prime}(\mathrm{t})=\frac{\partial g_{j}}{\partial t} \frac{d t}{d t}+\frac{\partial g_{j}}{\partial u_{1}} \frac{d u_{1}}{d t} \frac{\partial g_{j}}{\partial u_{2}} \frac{d u_{2}}{d t}+\ldots+\frac{\partial g_{j}}{\partial u_{k}} \frac{d u_{k}}{d t} .
$$

Substituting $g_{j}$ by $u_{j}^{\prime \prime}$, we get

$$
u_{j}^{\prime \prime \prime}(\mathrm{t})=\frac{\partial u_{j}^{\prime \prime}}{\partial t}+\frac{\partial u_{j}^{\prime \prime}}{\partial u_{1}} u_{1}^{I}+\frac{\partial u_{j}^{\prime \prime}}{\partial u_{2}} u_{2}^{I}+\ldots+\frac{\partial u_{j}^{\prime \prime}}{\partial u_{k}} u_{k}^{I}
$$

Repeating this process n-1 times until we reach $u_{j}^{(n)}$, then we get

$$
u_{j}^{(n)}(\mathrm{t})=\frac{\partial u_{j}^{(n-1)}}{\partial t}+\frac{\partial u_{j}^{(n-1)}}{\partial u_{1}} u_{1}^{I}+\frac{\partial u_{j}^{(n-1)}}{\partial u_{2}} u_{2}^{I}+\ldots+\frac{\partial u_{j}^{(n-1)}}{\partial u_{k}} u_{k}^{I}
$$

We note that every $u_{j}^{(i)}$ depends only on $u_{j}^{(i-1)}$ and the given $u_{j}^{I}$, where

$$
\begin{align*}
& \mathrm{i}=2, \ldots, \mathrm{n} ; \quad \mathrm{j}=1,2, \ldots, \mathrm{k} \text {. So, we can generalize that } \\
& u_{j}^{(i)}(\mathrm{t})=\frac{\partial u_{j}^{(i-1)}}{\partial t}+\frac{\partial u_{j}^{(i-1)}}{\partial u_{1}} u_{1}^{I}+\frac{\partial u_{j}^{(i-1)}}{\partial u_{2}} u_{2}^{I}+\ldots+\frac{\partial u_{j}^{(i-1)}}{\partial u_{k}} u_{k}^{I}, \tag{3.6}
\end{align*}
$$

where $i=2, \ldots, n$ and $j=1,2, \ldots, k$.
Putting (3.6) into summation form, we get
$u_{j}^{(i)}(t)=\frac{\partial u_{j}^{(i-1)}}{\partial t}+\sum_{p=1}^{k}\left(\frac{\partial u_{j}^{(i-1)}}{\partial u_{p}} u_{p}^{\prime}\right)$,
where $i=2, \ldots, n ; j=1,2, \ldots, k$.

In our programs, we will use matrices "up" of dimensions $\mathrm{k} \times \mathrm{n}$ to enter $u_{j}^{(i)}(\mathrm{t})$ in $u p(\mathrm{j}, \mathrm{i})$ where $\mathrm{i}=1, \ldots, \mathrm{n}, \mathrm{j}=1,2, \ldots, \mathrm{k}$. The notation $u p(\mathrm{j}$ ,i) and $\operatorname{up}(\mathrm{p}, 1)$ refer to $u_{j}^{(i)}$ and $u_{p}^{\prime}$, where $\mathrm{i}=1, \ldots, \mathrm{n}, \mathrm{j}=1, \ldots, \mathrm{k}$ and $\mathrm{p}=1$, $\ldots, \mathrm{k}$. Now for $\mathrm{i}=1, \mathrm{u}(\mathrm{j}, 1)$ is $u_{j}^{r}$. Thus, we can write (3.7) as follows:

$$
\begin{align*}
& u(j, 1)=u_{j}^{\prime} \\
& \text { For } j=1, \ldots, k \\
& \operatorname{up}(\mathrm{j}, \mathrm{i})=\frac{\partial u p(j, i-1)}{\partial t}+\sum_{p=1}^{k}\left[\frac{\partial u p(j, i-1)}{\partial u_{p}} u p(p, 1)\right], \mathrm{i}=2, \ldots, \mathrm{n} . \tag{3.8}
\end{align*}
$$

In the following subsections, we will first implement (3.7) in algorithms to find higher order derivatives of $u_{j}^{r}$ in each equation in the system of first order IVP's (3.4), and then use these derivatives to construct Taylor expansion of each $f_{j}\left(t, u_{1}, \ldots, u_{k}\right)$ and finally solve the system of IVP using higher order Taylor methods.

### 3.3.1 Finding Higher Order Derivatives of Systems of First Order IVP's

We put the iterative method (3.7) into Algorithm (3.4). In addition, we translated it into a Matlab Program (3.4). This program uses the alternative form (3.8) instead of (3.7) for finding the first n derivatives of $u_{j}^{r}(t) ; \mathrm{j}=2, \ldots, \mathrm{k}$.
Algorithm (3.4) Finds higher order derivatives of $\boldsymbol{u}_{j}^{\prime}(\boldsymbol{t})$ in the system of first order IVP's: $u_{j}^{\prime}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k$

To find higher order derivatives of $u_{j}^{\prime}(t)$ in the system of first order ODEs:
$u_{j}^{\prime}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k$
Step 1: Define number of equations $k$;
Step 2: Define the system $u_{j}^{(1)}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k$
Step 7: For $j=1$ to $k ; \quad$ Let $u_{p}(j, 1)=u_{j}^{(1)}(t)$
Step 3: For $i=2$ to $n$ repeat steps $4-8$
Step 4: $\quad$ For $j=1$ to $k$ repeat steps $5-8$
Step 5: $\quad$ Let $u_{j}^{(i)}=\partial u_{j}^{(i-1)} / \partial t$
Step 6: $\quad$ For $p=1$ to $k$ repeat steps $7-8$
Step 7: $\quad \operatorname{Let} u_{j}^{(i)}=u_{j}^{(i)}+\left(\partial u_{p}^{(i-1)} / \partial u_{p}\right) * u_{p}^{(1)}$

Step 8: $\quad$ Let $u_{p}(j, i)=u_{j}^{(i)}$
Step 9: Output $u_{p}$
Step 10: Stop

## Example (3.6)

For $\mathrm{n}=3$ and 6 , we can find the first $\mathrm{n}-1$ derivatives of each $\mathrm{u}_{\mathrm{j}}^{I}$ of the
following system with respect to t , where $u_{j}$ are functions of t and $\mathrm{j}=1,2,3$.
$\mathrm{u}_{1}^{I}=\mathrm{u}_{2}-\mathrm{u}_{3}+\mathrm{t}$,
$\mathrm{u}_{2}^{r}=3 \mathrm{t}^{2}$,
$\mathrm{u}_{3}^{r}=\mathrm{u}_{2}+\mathrm{e}^{-\mathrm{t}}$.
Running Program (3.4), entering the system and three for $n$, gives the following results:

$$
\begin{aligned}
& {\left[\mathrm{u}_{1}^{\prime}, \mathrm{u}_{1}^{\prime \prime}, \mathrm{u}_{1}^{s \prime \prime}\right]=\left[\mathrm{u} 2-\mathrm{u} 3+\mathrm{t}, 1+3^{*} \mathrm{t} \wedge 2-\mathrm{u} 2-\exp (-\mathrm{t}), 6^{*} \mathrm{t}+\exp (-\mathrm{t})-3^{*} \mathrm{t}^{\wedge} 2\right]} \\
& {\left[\mathrm{u}_{2}^{I}, \mathrm{u}_{2}^{I I}, u_{2}^{I \prime \prime}\right]=\left[\quad 3 * \mathrm{t}^{\wedge} 2,6^{*} \mathrm{t}, 6\right]} \\
& {\left[\mathrm{u}_{3}^{I}, \mathrm{u}_{3}^{I I}, u_{3}^{I \prime \prime}\right]=\left[\mathrm{u} 2+\exp (-\mathrm{t}),-\exp (-\mathrm{t})+3 * \mathrm{t}^{\wedge} 2,6^{*} \mathrm{t}+\exp (-\mathrm{t})\right]}
\end{aligned}
$$

Repeating running the program for the same system but for $n=4$, gives the following results:

$$
\begin{aligned}
& {\left[\mathrm{u}_{1}^{I}, \mathrm{u}_{1}^{I I}, \mathrm{u}_{1}^{I I I}, \mathrm{u}_{1}^{(4)}\right]=\left[\mathrm{u} 2-\mathrm{u} 3+\mathrm{t}, 1+3^{*} \mathrm{t}^{\wedge} 2-\mathrm{u} 2-\exp (-\mathrm{t}),\right.} \\
& \\
& \left.\quad 6^{*} \mathrm{t}+\exp (-\mathrm{t})-3^{*} \mathrm{t}^{\wedge} 2, \quad 6-\exp (-\mathrm{t})-6^{*} \mathrm{t}\right] \\
& {\left[\mathrm{u}_{2}^{I}, \mathrm{u}_{2}^{I I}, \mathrm{u}_{2}^{I I \prime}, \mathrm{u}_{2}^{(4)}\right]=\left[3^{*} \mathrm{t}^{\wedge} 2,6^{*} \mathrm{t}, 6,0\right]} \\
& {\left[\mathrm{u}_{3}^{I}, \mathrm{u}_{3}^{I I}, \mathrm{u}_{3}^{I \prime \prime}, \mathrm{u}_{3}^{(4)}\right]=\left[\mathrm{u} 2+\exp (-\mathrm{t}),-\exp (-\mathrm{t})+3^{*} \mathrm{t}^{\wedge} 2,6^{*} \mathrm{t}+\exp (-\mathrm{t}), 6-\exp (-\mathrm{t})\right]}
\end{aligned}
$$

### 3.3.2 Constructing Taylor Expansion for a System of First Order IVP's

Taylor expansion for $f(t, y)$ of first order IVP as defined in (2.8)

$$
T^{(n)}(\mathrm{t}, \mathrm{y}, \mathrm{~h})=\mathrm{y}^{\prime}+\frac{h}{2} \mathrm{y}^{\prime \prime}+\ldots+\frac{h^{n-1}}{n!} \mathrm{y}^{(\mathrm{n})} .
$$

Now for the system (3.3), the nth Taylor expansion of $f_{j}\left(t, u_{1}, \ldots, u_{k}\right)$ will be

$$
\begin{equation*}
T_{j}^{(n)}\left(\mathrm{t}, \mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{k}}, \mathrm{~h}\right)=\mathrm{u}_{\mathrm{j}}^{\prime}+\frac{h}{2!} \mathrm{u}_{\mathrm{j}}^{\prime \prime}+\cdots+\frac{h^{n-1}}{n!} \mathrm{u}_{\mathrm{j}}^{(\mathrm{n})} ; \mathrm{j}=1, \ldots, \mathrm{k} . \tag{3.9}
\end{equation*}
$$

Algorithm (3.5) constructs the array T, where $T_{j}$ refers to $T_{j}^{(n)}$ defined in the system (3.3). It includes the steps used in Algorithm (3.4), in addition to the steps needed to generate (3.9).

We translated Algorithm (3.5) into Matlab Program (3.5). It constructs the array $T$, where $T(j)$ refers to $T_{j}^{(n)}$ in equation (3.9).

## Algorithm (3.5) Constructs $T_{j}$ 's as Taylor expansions of each $u_{j}^{\prime}(t)$ in the

 system of first order IVPs: $\quad u_{j}^{\prime}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k$To construct the array $T$, where $T_{j}$ is the Taylor expansion of $u_{j}^{\prime}(t)$ by first finding higher order derivatives of $u_{j}^{\prime}(t)$ in the system of first order ODEs:

$$
u_{j}^{\prime}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k
$$

Step 1: Define number of the equations $k$;
Step 2: Define the system $u_{j}^{(1)}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right)$
Step 3: For $j=1$ to $k$ repeat steps 5-6
Step 5: $\quad \operatorname{Let} u p(j, 1)=u_{j}^{(1)}(t)$
Step 6: $\quad \operatorname{Let} T_{j}\left(t, u_{1}, \ldots, u_{k}, h\right)=u_{j}^{(1)}(t)$
Step 7: Let fac $=1$
Step 8: For $i=2$ to $n$ repeat steps $9-15$
Step 9: Let fac $=f a c * i$
Step 10: $\quad$ For $j=1$ to $k$ repeat steps $11-15$

Step 11: $\quad \operatorname{Let} u_{j}^{(i)}=\partial u_{j}^{(i-1)} / \partial t$
Step 12: $\quad$ For $p=1$ to $k$ repeat step 13
Step 13: Let $u_{j}^{(i)}=u_{j}^{(i)}+\left(\partial u_{p}^{(i-1)} / \partial u_{p}\right) * u_{p}^{(1)}$
Step 14: $\quad$ Let $u p(j, i)=u_{j}^{(i)}$
Step 15: $\quad T_{j}\left(t, u_{1}, \ldots, u_{k}, h\right)=T_{j}\left(t, u_{1}, \ldots, u_{k}, h\right)+\left(h^{i-1} /\right.$ fac $) * u p(j, i)$
Step 16: Output T

Step 16: Stop

## Example (3.7)

Consider constructing T for the system in Example (3.6) using $\mathrm{n}=2$ and $\mathrm{n}=4$.
Running Program (3.4), entering the system and n , results:
For $\mathrm{n}=2$

$$
\begin{aligned}
& \mathrm{T}(1)=(\mathrm{u} 2-\mathrm{u} 3+\mathrm{t})+1 / 2 * \mathrm{~h} *(1+3 * \mathrm{t} \wedge 2-\mathrm{u} 2-\exp (-\mathrm{t})), \\
& \mathrm{T}(2)=3 * \mathrm{t}^{\wedge} 2+3 * \mathrm{~h} * \mathrm{t}, \\
& \mathrm{~T}(3)=(\mathrm{u} 2+\exp (-\mathrm{t}))+1 / 2 * \mathrm{~h} *\left(-\exp (-\mathrm{t})+3 * \mathrm{t}^{\wedge} 2\right) .
\end{aligned}
$$

For $\mathrm{n}=4$

$$
\begin{aligned}
& \mathrm{T}(1)=(\mathrm{u} 2-\mathrm{u} 3+\mathrm{t})+1 / 2 * \mathrm{~h}^{*}\left(1+3 * \mathrm{t}^{\wedge} 2-\mathrm{u} 2-\exp (-\mathrm{t})\right)+1 / 6 * \mathrm{~h}^{\wedge} 2 \\
& *\left(6 * \mathrm{t}+\exp (-\mathrm{t})-3 * \mathrm{t}^{\wedge} 2\right)+1 / 24 * \mathrm{~h}^{\wedge} 3 *(6-\exp (-\mathrm{t})-6 * \mathrm{t}), \\
& \mathrm{T}(2)=3 * \mathrm{t}^{\wedge} 2+3 * h^{*} \mathrm{t}+\mathrm{h}^{\wedge} 2, \\
& \mathrm{~T}(3)=(\mathrm{u} 2+\exp (-\mathrm{t}))+1 / 2 * \mathrm{~h}^{*}\left(-\exp (-\mathrm{t})+3 * \mathrm{t}^{\wedge} 2\right)+1 / 6 * \mathrm{~h}^{\wedge} 2 \\
& \\
& *(6 * t+\exp (-\mathrm{t}))+1 / 24^{*} \mathrm{~h}^{\wedge} 3^{*}(6-\exp (-\mathrm{t})) .
\end{aligned}
$$

### 3.3.3 Higher Order Taylor Methods for Systems of First Order IVP's

From previous discussions, we have the iterative method (2.16) for a single equation IVP

$$
w_{i+1}=w_{i}+h T\left(t_{i}, w_{i}, h\right), \quad i=1,2, \ldots, N
$$

and Taylor expansion "equation (3.9)" for a system of IVP

$$
T_{j}^{(n)}\left(\mathrm{t}, \mathrm{u}_{1}, \ldots, \mathrm{u}_{\mathrm{k}}, \mathrm{~h}\right)=\mathrm{u}_{\mathrm{j}}^{\prime}+\frac{h}{2!} \mathrm{u}_{\mathrm{j}}^{\prime \prime}+\ldots+\frac{h^{n-1}}{n!} \mathrm{u}_{\mathrm{j}}^{(\mathrm{n})} ; \mathrm{j}=1, \ldots, \mathrm{k} .
$$

Combining these equations, we get the iterative method for approximating the solution of a system of first order IVP.
$w_{j, i+1}=w_{j, i}+h T_{j}^{(n)}\left(t_{i}, w_{1, i}, . ., w_{k, i}\right)$
$i=1,2, \ldots, N, \quad j=1,2, \ldots, k$
In Algorithm (3.6), we changed Taylor method we used in Algorithm (3.3), by using equation (3.10), to deal with systems of equations instead of one equation. Algorithm (3.6) approximates the solution (w)of a system of first order IVP, finds the exact solution (uN) and global error (error), using different orders n and different step sizes h . We put this algorithm into a Matlab Program (3.6) that we will use in approximating the solution of systems of first order ordinary differential equations initial value problems.
Algorithm (3.6): Solves the system $u_{j}^{\prime}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k$ by higher order Taylor methods

$$
\text { To solve the system } \quad u_{j}^{\prime}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k
$$

by higher order Taylor method
Step 1: Define number of equations $k$;
Step 2: Define the system $u_{j}^{(1)}(t)=f_{j}\left(t, u_{1}, \ldots, u_{k}\right), j=1, \ldots, k$

```
Step 3: Define the functions fuEx \(x_{1}(t), \ldots, f u E x_{k}(t)\)
Step 4: Define endpoints \(a, b\)
Step 5: Define initial conditions \(u N_{1,1}=\alpha_{1}, \ldots, u N_{k, 1}=\alpha_{k}\)
Step 6: Define step size \(h\);Taylor's order \(n\)
Step 7: Use algorithm (3.5) to get \(T\left(t, u_{1}, \ldots, u_{k}, h\right)\)
Step 8: Let \(t_{1}=a\)
Step 9: Let \(N=(b-a) / h\)
Step10: For \(j=1\) to \(k\) repeat Let \(w_{j, 1}=u N_{j, 1}\)
Step 11: For \(i=1\) to \(N\) repeat steps \(12-15\)
Step 12: \(\quad\) For \(j=1\) to \(k\) repeat steps \(13-14\)
Step 13: Let \(w_{j, i+1}=w_{j, i}+h * T_{j}\left(t, w_{1, i}, \ldots, w_{k, i}, h\right)\)
Step 14: \(\quad\) Let \(u N_{j, i+1}=f u E x_{j}\left(t_{i+1}\right)\)
Step 15: \(\quad t_{i+1}=t_{i}+h\)
Step 16: \(G E=a b s(u N-w)\)
Step 17: Output \(t, u N, w, G E\)
Step 18: Stop
```

## Example (3.8)

We can find an approximate solution to the following system using $\mathrm{h}=0.1$ and Taylor order $\mathrm{n}=4$ :

$$
\begin{aligned}
& u_{1}^{\prime}=-4 \mathrm{u}_{1}+3 \mathrm{u}_{2}+6, \\
& u_{2}^{\prime}=-2.4 \mathrm{u}_{1}+1.6 \mathrm{u}_{2}+3.6, \\
& \mathrm{u}_{1}(0)=0, \quad \mathrm{u}_{2}(0)=0, \quad 0<\mathrm{t}<1 .
\end{aligned}
$$

Actual solution of the system

$$
\begin{aligned}
& u_{1}(t)=-3.375 e^{-2 t}+1.875 e^{-0.4 t}+1.5 \\
& u_{2}(t)=-2.25 e^{-2 t}+2.25 e^{-0.4 t}
\end{aligned}
$$

The generated Taylor method (h is replaced by its value 0.1)

$$
\begin{aligned}
& w_{1, i+1}=w_{1, i}+h T_{1}\left(t_{i}, w_{1, i}, w_{2, i}\right) \text { for approximation of } u_{1}, i=1, \ldots, N . \\
& w_{2, i+1}=w_{2, i}+h T_{2}\left(t_{i}, w_{1, i}, w_{2, i}\right) \text { for approximation of } u_{2}, i=1, \ldots, N
\end{aligned}
$$

where

$$
\begin{aligned}
& \mathrm{T}_{1}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}\right)=-224273 / 62500 * \mathrm{u} 1+41618 / 15625^{*} \mathrm{u} 2+672819 / 125000, \\
& \mathrm{~T}_{2}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}\right)=-166472 / 78125^{*} \mathrm{u} 1+1297121 / 937500 * \mathrm{u} 2+249708 / 78125 .
\end{aligned}
$$

Table (3.2) contains exact values, approximated values and errors at each $t_{i}$ for each $u$ in the system of Example (3.8).

Table (3.2): Results of Example (3.8) using fourth order Taylor's method using $h=0.1$

Figure (3.2) contains plotted results of Example (3.8). It contains four curves; $\mathrm{u}_{1}$ and $\mathrm{u}_{2}$ represent the exact solutions, while $\mathrm{w}_{1}$ and $\mathrm{w}_{2}$ represent the approximated solutions of $u_{1}$ and $u_{2}$. We notice that the curves of $w_{1}$ and $w_{2}$ coincide with the curves of $u_{1}$ and $u_{2}$ respectively. That means that we have good results.

Figure (3.2): Results of Example (3.8)

## Example (3.9)

We can find an approximate solution of the following system of IVP.
Take $\mathrm{n}=9$ and $\mathrm{h}=0.1$.

$$
\begin{aligned}
& u_{1}^{\prime}=\mathrm{u}_{2}-\mathrm{u}_{3}+\mathrm{t}, \\
& u_{2}^{\prime}=3 t^{2}, \quad 0 \leq \mathrm{t} \leq 1 \\
& u_{3}^{\prime}=\mathrm{u}_{2}+\mathrm{e}^{(-\mathrm{t})}, \mathrm{h}=0.1
\end{aligned}
$$

with initial conditions

$$
\mathrm{u}_{1}(0)=1, \quad u_{2}(0)=1 \quad \text { and } \quad u_{3}(0)=-1 .
$$

This system has the exact solution

$$
\begin{aligned}
& u_{1}(t)=-0.05 t^{5}+0.25 t^{4}+t+2-e^{-t}, \\
& u_{2}(t)=t^{3}+1, \text { and } \\
& u_{3}(t)=0.25 t^{4}+t-e^{-t} .
\end{aligned}
$$

We ran Program (3.6) for this problem and it produced the following results:

- The generated Taylor method ( h is replaced by its value 0.1 )

$$
\mathrm{w}_{1, \mathrm{i}+1}=\mathrm{w}_{1, \mathrm{i}}+\mathrm{h} \mathrm{~T}_{1}\left(\mathrm{t}_{\mathrm{i}}, \mathrm{w}_{1, \mathrm{i},}, \mathrm{w}_{2, \mathrm{i}}, \mathrm{w}_{3, \mathrm{i}}\right) \text { for approximation of } \mathrm{u}_{1}, \mathrm{i}=1, \ldots, \mathrm{~N},
$$

$\mathrm{w}_{2, \mathrm{i}+1}=\mathrm{w}_{2, \mathrm{i}}+\mathrm{hT} \mathrm{T}_{2}\left(\mathrm{t}_{\mathrm{i}}, \mathrm{w}_{1, \mathrm{i}}, \mathrm{w}_{2, \mathrm{i}}, \mathrm{w}_{3, \mathrm{i}}\right)$ for approximation of $\mathrm{u}_{2}, \mathrm{i}=1, \ldots, \mathrm{~N}$, $\mathrm{w}_{3, \mathrm{i}+1}=\mathrm{w}_{3, \mathrm{i}}+h \mathrm{~T}_{2}\left(\mathrm{t}_{\mathrm{i}}, \mathrm{w}_{1, \mathrm{i}}, \mathrm{w}_{2, \mathrm{i}}, \mathrm{w}_{3, \mathrm{i}}\right)$ for approximation of $\mathrm{u}_{3}, \mathrm{i}=1, \ldots, \mathrm{~N}$, where

$$
\begin{gathered}
\mathrm{T}_{1}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \mathrm{u}_{3}\right)=19 / 20 * \mathrm{u} 2-\mathrm{u} 3+4039 / 4000 * \mathrm{t}+14829706495736582734389 \\
/ 295147905179352825856000+29 / 200 * \mathrm{t}^{\wedge} 2
\end{gathered}
$$

$$
-122643117536780316708704412413253
$$

/2535301200456458802993406410752000*exp(-t),

$$
\mathrm{T}_{2}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \mathrm{u}_{3}\right)=3 * \mathrm{t}^{\wedge} 2+3 / 10 * \mathrm{t}+1 / 100
$$

$$
\mathrm{T}_{3}\left(\mathrm{t}, \mathrm{u}_{1}, \mathrm{u}_{2}, \mathrm{u}_{3}\right)=\mathrm{u} 2+2412658082919678486284701998338747
$$

/2535301200456458802993406410752000

$$
* \exp (-t)+3 / 20 * t^{\wedge} 2+1 / 100 * t+1 / 4000
$$

- Table (3.3) contains exact values, approximated values and errors at each $t_{i}$ for each $u$ in the system of Example (3.9). We have very good results, since the global errors at the final step is about $10^{-15}$, which is better than the expected $\mathrm{O}\left(\mathrm{h}^{9}\right)$.
- Figure (3.3) contains plotted results of Example (3.9). It contains six curves; $\mathrm{u}_{1}, \mathrm{u}_{2}$ and $\mathrm{u}_{3}$ represent the exact solutions, while $\mathrm{w}_{1}, \mathrm{w}_{2}$ and $\mathrm{w}_{3}$ represent the approximated solutions of $u_{1}, u_{3}$ and $u_{3}$. We notice that the curves of $w_{1}, w_{2}$ and $w_{3}$ coincide with the curves of $u_{1}, u_{2}$ and $u_{3}$ respectively. That means that we have good results.

Figure (3.3): Results of Example (3.9)

### 3.4 Higher Order Taylor Methods for Higher Order IVP's

In this section, we will develop an algorithm, which we will translate into a Matlab program to approximate the solution of the IVP (1.4)

$$
\begin{aligned}
& \mathrm{y}^{(\mathrm{k})}(\mathrm{t})=f\left(\mathrm{t}, \mathrm{y}, y^{\prime}, y^{\prime \prime}, \ldots, y^{(k-1)}\right), \quad \mathrm{a} \leq \mathrm{t} \leq \mathrm{b}, \\
& \mathrm{y}(\mathrm{a})=\alpha_{1}, y^{\prime}(\mathrm{a})=\alpha_{2}, y^{\prime \prime}(\mathrm{a})=\alpha_{3}, \ldots, y^{(k-1)}(\mathrm{a})=\alpha_{\mathrm{k}} .
\end{aligned}
$$

To approximate the solution of a higher order IVP, we first transform it into a system (1.7) of first order IVP's as discussed in chapter one. Then, we approximate the solution of the system satisfying the initial conditions. Finally, we treat the approximated $w_{1}$ of $u_{1}$ as the approximation of $y$.

Algorithm (3.7) solves higher order ordinary differential equations initial value problem
$y^{(k)}(t)=f\left(\mathrm{t}, \mathrm{y}, \mathrm{y}^{\prime}, \mathrm{y}^{\prime \prime}, \ldots, y^{(\mathrm{k}-1)}\right), \quad a \leq t \leq b$,
$\mathrm{y}(\mathrm{a})=\alpha_{1}, \quad \mathrm{y}^{\prime}(\mathrm{a})=\alpha_{2}, \ldots, \mathrm{y}^{(\mathrm{k}-1)}(\mathrm{a})=\alpha_{\mathrm{k}}$,
following the steps mentioned in the last paragraph.

## Algorithm (3.7): Solves higher order IVP's by higher order Taylor methods

To solve the ODE $y^{(k)}(t)=f\left(\mathrm{t}, \mathrm{y}, \mathrm{y}^{\prime}, \mathrm{y}^{\prime \prime}, \ldots, y^{(\mathrm{k}-1)}\right)$, by converting it into a system of first order ODEs and then solve the system by higher order Taylor methods
Step 1: Define order of the ODE $k$;
Step 2: Define the ODE $y^{(k)}(t)=f\left(\mathrm{t}, \mathrm{y}, \mathrm{y}^{\prime}, \mathrm{y}^{\prime \prime}, \ldots, y^{(\mathrm{k}-1)}\right)$;
Step 3: Define the exactfunction fyEx $(t)$
Step 4: Define endpoints $a, b$
Step 5: Define initial conditions $\mathrm{y}(\mathrm{a})=\alpha_{1}, \mathrm{y}^{\prime}(\mathrm{a})=\alpha_{2}, \ldots, \mathrm{y}^{(\mathrm{k}-1)}(\mathrm{a})=\alpha_{\mathrm{k}}$
Step 6: Define step size $h_{\text {; Taylor's }}$ order $n$

$$
\begin{array}{|lc|}
\text { Step 7: } & \text { Let } y=u_{1} ; \mathrm{uN}_{1}=\mathrm{y}(\mathrm{a}) \\
\text { Step 8: } & \text { For } i=1 \text { to }(k-1) \text { repeat steps } 9-11 \\
\text { Step 9: } & \text { Let } u_{i}^{\prime}=u_{i+1} \\
\text { Step 10: } & \text { Let } y^{(i)}=u_{i+1} \\
\text { Step 11: } & \quad \mathrm{uN}_{\mathrm{i}+1}=y^{(i)}(\mathrm{a}) \\
\text { Step 12: } & \text { Let } u_{k}^{\prime}=f\left(\mathrm{t}, \mathrm{y}, \mathrm{y}^{\prime}, \mathrm{y}^{\prime \prime}, \ldots, y^{(\mathrm{k}-1)}\right) ; \text { Note:This results } u_{k}^{\prime}=f\left(t, u_{1}, \ldots, u_{k}\right) \\
\text { Step 13: } & \text { Use algorithm }(3.5) \text { to get } T\left(t, u_{1}, \ldots, u_{k}, h\right) \\
\text { Step 14: } & \text { Let } t_{1}=a \\
\text { Step 15: } & \text { Let } N=(b-a) / h \\
\text { Step 16: } & \text { For } j=1 \text { to } k \text { repeat } \quad \text { Let } w_{j, 1}=u N_{j} \\
\text { Step 17: } & \text { Let } y N_{1}=u N_{1} \\
\text { Step 18: } & \text { For } i=1 \text { to } N \text { repeat steps } 19-22 \\
\text { Step 19: } & \text { For } j=1 \text { to } k \text { repeat step } 20 \\
\text { Step 20: } & \quad \text { Let } w_{j, i+1}=w_{j, i}+h * T_{j}\left(t, w_{1, i}, \ldots, w_{k, i}, h\right) \\
\text { Step 21: } & t_{i+1}=t_{i}+h \\
\text { Step 22: } & \text { Let } y N_{i+1}=\text { fyEx }\left(t_{i+1}\right) \\
\text { Step 23: } & \text { GE }=\text { abs }\left(y N-w_{1,1: N+1}\right) \\
\text { Step 24: } & \text { Output } t, y N, w_{1,1: N+1}, \text { GE } \\
\text { Step 25: } & \text { Stop }
\end{array}
$$

We translated Algorithm (3.7) into the Matlab Program (3.7), which we will use in solving the following examples.

## Example (3.10)

We can transform the following IVP into a system of first order s , and then approximate the solution of $\mathrm{y}(\mathrm{t})$ using $\mathrm{n}=4$ and $\mathrm{h}=0.1$.
$\mathrm{y}^{(10)}(\mathrm{t})=2 \mathrm{y}^{(9)}+\mathrm{y}^{(8)}(\mathrm{t})-3 \mathrm{y}^{(7)}(\mathrm{t})+2 \mathrm{y}^{(3)}(\mathrm{t})+\mathrm{y}^{\prime}(\mathrm{t})+\mathrm{y}(\mathrm{t})-(\exp (-\mathrm{t})+\mathrm{t}+1), 0 \leq t \leq 1$,
with initial conditions

$$
\begin{aligned}
& \mathrm{y}(0)=-1, y^{\prime}(0)=2, y^{\prime \prime}(0)=-1, y^{\prime \prime \prime}(0)=1, y^{(4)}(0)=-1, y^{(5)}(0)=1, \\
& y^{(6)}(0)=-1, y^{(7)}(0)=1, y^{(8)}(0)=-1 \text { and } y^{(9)}(0)=1 .
\end{aligned}
$$

Actual solution is

$$
y(t)=t-e^{-t}
$$

Running Program (3.7) for this problem gives the following results:
The generated System

$$
\begin{aligned}
& u 1^{\prime}=u 2 ; \quad u 1(0)=-1 \quad u 2^{\prime}=u 3 ; \quad u 2(0)=2 \\
& u 3^{\prime}=u 4 ; \quad u 3(0)=-1 \quad u 4^{\prime}=u 5 ; \quad u 4(0)=1 \\
& u 5^{\prime}=u 6 ; \quad u 5(0)=-1 \quad u 6^{\prime}=u 7 ; u 6(0)=1 \\
& u 7^{\prime}=u 8 ; \quad u 7(0)=-1 \quad u 8^{\prime}=u 9 ; u 8(0)=1 \\
& u 9^{\prime}=u 10 ; \quad u 9(0)=-1 \\
& u 10^{\prime}=2 * u 10+u 9-3 * u 8+2 * u 4+u 2+u 1-\exp (-t)-t-1 \text {; } \\
& u 10(0)=1 \text {. }
\end{aligned}
$$

Table (3.4) contains t , exact solution $\mathrm{y}, w_{1}, \ldots, w_{10}$ approximating $u_{1}, \ldots, u_{10}$ and "error". The vector error is the absolute value of column two minus column one. We are interested only on the vector $w_{1}$, since it approximates $u_{1}$, which is equal to y . That means $w_{1}$ approximates y .

Figure (3.4) shows that the curve of $\mathrm{w}_{1}$ coincides with the curve of y . This Figure shows only three of the nine remaining curves of $w_{2}, \ldots, w_{10}$ since $u_{3}^{r}=u_{5}^{I}=u_{7}^{r}=u_{7}^{r}$ and $u_{4}^{r}=u_{6}^{r}=u_{8}^{r}=u_{10}^{r}$. In addition we used circles in plotting all curves of $\mathrm{w}_{2}, \ldots, \mathrm{w}_{10}$.

Figure (3.4): Results of Example (3.10)

## Example (3.11)

We can find an approximate solution to following IVP using step size $\mathrm{h}=0.1$ and Taylor of order $\mathrm{n}=15$ :

$$
\mathrm{y}^{(20)}(\mathrm{t})=\mathrm{y}(\mathrm{t}), \quad 0 \leq \mathrm{t} \leq 2,
$$

with initial conditions

$$
\mathrm{y}^{(\mathrm{i})}(0)=(-1)^{\mathrm{i}}, \mathrm{i}=0, \ldots, 19 .
$$

Exact solution for the IVP is

$$
y(t)=e^{-t} .
$$

Running Program (3.7) for this problem gives the following results:

The generated System

$$
\begin{array}{llll}
u 1^{\prime}=u 2 ; & u 1(0)=-1 & u 2^{\prime}=u 3 ; & u 2(0)=1 \\
u 3^{\prime}=u 4 ; & u 3(0)=-1 & u 4^{\prime}=u 5 ; & u 4(0)=1 \\
u 5^{\prime}=u 6 ; & u 5(0)=-1 & u 6^{\prime}=u 7 ; & u 6(0)=1 \\
u 7^{\prime}=u 8 ; & u 7(0)=-1 & u 8^{\prime}=u 9 ; & u 8(0)=1 \\
u 9^{\prime}=u 10 ; & u 9(0)=-1 & u 10^{\prime}=u 11 ; & u 10(0)=1
\end{array}
$$

$$
\begin{array}{lll}
u 11^{\prime}=u 12 ; & u 11(0)=-1 & u 12^{\prime}=u 13 ; \\
u 12(0)=1 \\
u 13^{\prime}=u 14 ; & u 13(0)=-1 & u 14^{\prime}=u 15 ; \\
u 14(0)=1 \\
u 15^{\prime}=u 16 ; & u 15(0)=-1 & u 16^{\prime}=u 17 ; \\
u 16(0)=1 \\
u 17^{\prime}=u 18 ; & u 17(0)=-1 & u 18^{\prime}=u 19 ; \\
u 19^{\prime}=u 20 ; & u 19(0)=-1 & u 20^{\prime}=u 1 ; \\
u 20(0)=1 .
\end{array}
$$

Table (3.5) contains the vectors $t, y, w_{1}$ and $G E$. Since we are interested only on $w_{1}$, we haven't presented $w_{2}, \ldots, w_{20}$ in Table (3.5). We still have good results, but not as good as in the previous example, since we have used order fifteen.

Table (3.5): Results of Example (3.11), using Taylor of order n=15 and step size $\mathbf{h = 0 . 1}$

Figure (3.5) shows that the curve of $w_{1}$ coincides with the curve of $y$. As earlier explained, we plotted only $y$ and $w_{1}$.

Figure (3.5): Comparison between the approximated solution $w_{1}$ and the exact solution $y$ in Example (3.11) with $n=15, h=0.1$

## Chapter Four

## Error Analysis

### 4.1 Error Analysis for Numerical Methods

In this section, we will study the global error (GE) generated by fourth order numerical methods studied in chapter two. These are Taylor method, Runge-Kutta method, Adams-Bashforth method, Adams-Moulton method, predictor-corrector method and Milne's method. Using step size $h=0.1$, we will apply all of these methods to the initial value problem in the next example.

## Example (4.1)

Using step size $h=0.1$, we can approximate the solution to the IVP
$y^{\prime}(t)=\frac{-2 y}{t}+4 t, \quad 0.5 \leq t \leq 1.5, \quad y(0.5)=4.25$.
This initial value problem has the exact solution
$y(t)=t^{2}+\frac{1}{t^{2}}$.
For $t \in[0.5,1.5]$ and $h=0.1$, we have $t_{1}=0.5$ and $t_{i}=0.5+0.1(i-1)$, $i=2, \ldots, 11$. We will approximate the solution and compare it with the given exact solution of (4.1) at these values of $t$.

Table (4.1) contains the numerical results for fourth order Taylor method generated for initial value problem (4.1).

Table (4.1): Results of problem (4.1) using Taylor method

| $t_{i}$ | $y_{i}$ | $w_{i}$ | $\left\|G E_{i}\right\|$ |
| :---: | :---: | :---: | :---: |
| 0.5 | 4.2500000 | 4.2500000 | $0.0000000 \mathrm{E}+00$ |

(4.1) against t .

Figure (4.5): Approximate and exact solutions for problem (4.1) using fourth order predictor-corrector method

Since Adams-Moulton method is an implicit method, we had to solve manually for $w_{i+1}$. We found that
$w_{i+1}=\frac{4 t_{i+1}}{4 t_{i+1}+3 h}\left[w_{i}+\frac{3 h t_{i+1}}{2}+\frac{h}{24}\left(19 f_{i}-5 f_{i-1}+f_{i-2}\right)\right]$

Table (4.6) contains the numerical results for fourth order Adams-Moulton method generated for initial value problem (4.1).

Table (4.6): Results of problem (4.1) using Adams-Moulton method

Figure (4.6): Approximate and exact solutions for problem (4.1) using fourth order Adams-Moulton method

Since we used the RK method to approximate the starting values for the multistep methods, we thought that it would be not accurate to compare them with other methods in such manner. Therefore, we modified the programs to assign exact values to $w_{i}$ at the first four steps $(t=0.5,0.6,0.7,0.8)$ and let the methods approximate the solution at the remaining points.

Table (4.7) contains global errors for these six methods. Since we assigned $w_{1}, w_{2}, w_{3}, w_{4}$ exact values, global errors at $t_{1}, t, t_{3}, t_{4}$ will be zero for all methods.

Table (4.7): Errors generated by the methods used to solve Example (4.1)

| $t_{i}$ | RK | Taylor | Adams- <br> Moulton | Predictor- <br> Corrector | Adams- <br> Bashforth | Milne |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Figure (4.7): (a) Propagation of GE by the six methods in study for Example (4. 1)

Figure (4.7): (b) Closer look into the first 4 methods with least error

Figure (4.7) (a) shows error propagation of the six methods under study. It is clear that Milne's method is the method with greatest error. To have a better comparison for the methods, we excluded in Figure (4.7) (b) the curves of

Milne's and Adams-Bashforth. Figure (4.7) (a) shows that RK method generated the least error.

To do more analysis to the data in Table (4.7), we took the absolute global errors, accumulated by using each of these six methods, at the last step $t=1.5$, sorted them in ascending order and put them into Table (4.8) column 2. We found that RK method has the smallest error, while Milne's method has the greatest error. In addition, Table (4.8) contains the error ratios of these methods. For example, the ratio of the error generated by AdamsBashforth method to the error generated by Adams-Moulton method is about 28:1.

Table (4.8): Error ratios for the methods under study

| order | error at <br> $\mathrm{t}=1.5$ | Method | Runge- <br> Kutta | Taylor | Adams- <br> Moulton | Predictor- <br> Corrector | Adams- <br> Bashforth | Milne |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $9.6474 \mathrm{E}-06$ | Runge- <br> Kutta | 1 |  |  |  |  |  |
| 2 | $2.1029 \mathrm{E}-04$ | Taylor | 21.798 | 1 |  |  |  |  |
| 3 | $9.2199 \mathrm{E}-04$ | Adams- <br> Moulton | 95.569 | 4.384 | 1 |  |  |  |
| 4 | $3.0423 \mathrm{E}-03$ | Predictor- <br> Corrector | 315.349 | 14.467 | 3.300 | 1 |  |  |
| 5 | $2.6018 \mathrm{E}-02$ | Adams- <br> Bashforth | 2696.897 | 123.723 | 28.219 | 8.552 | 1 |  |
| 6 | $5.8328 \mathrm{E}-02$ | Milne | 6045.966 | 277.36 <br> 4 | 63.263 | 19.172 | 2.242 | 1 |

Figure (4.8): Error accumulated at the last step in the methods under study in Example (4.1)

Table (4.8) shows that the error ratio is 1:3.300:28.219 for AdamsMoulton, Predictor-Corrector and Adams-Bashforth methods respectively. This means, using the implicit Adams-Moulton method as a corrector for the explicit Adams-Bashforth method has reduced the error by 8.552 times.

Surprisingly, both Table (4.8) and Figure (4.8) shows that one-step methods (RK and Taylor) are supreme to multistep methods of the same order.

To confirm our results, we will solve another example, using exact values at the first four steps as we done in the previous example.

## Example (4.2)

Using step size $h=0.1$, approximate the solution to the IVP
$y^{\prime}(t)=\frac{2-2 t y}{t^{2}+1}+4 t, \quad 0 \leq t \leq 1, \quad y(0)=1$.
This initial value problem has the exact solution
$y(t)=\frac{2 t+1}{t^{2}+1}$.
We represented global errors generated by the methods in Table (4.9), plotted this data in Figure (4.9) and calculated error ratios in Table (4.10).

Table (4.9): Global error generated in Example (4.2)

| $t_{i}$ | Adams- <br> Bashforth | Milne | Predictor- <br> Corrector | Adams- <br> Moulton | Taylor | RK |

Figure (4.9): (a) Propagation of GE by the methods under study for Example (4.2)

Figure (4.9): (b) Closer look into the first 4 methods with least error

Figure (4.9): (c) Closer look into the 2 methods with greatest error
Table (4.10): Error ratios of the methods under study for Example (4.2)

| order | error at <br> t=1.5 | method | RK | Taylor | Adams- <br> Moulton | Predictor- <br> Corrector | Milne | Adams- <br> Bashforth |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | $1.39 \mathrm{E}-06$ | RK | 1 |  |  |  |  |  |
| 2 | $2.97 \mathrm{E}-05$ | Taylor | 21.334 | 1 |  |  |  |  |
| 3 | $9.81 \mathrm{E}-05$ | Adams- <br> Moulton | 70.547 | 3.307 | 1 |  |  |  |
| 4 | $1.50 \mathrm{E}-04$ | Predictor- <br> Corrector | 107.761 | 5.051 | 1.528 | 1 |  |  |
| 5 | $2.78 \mathrm{E}-04$ | Milne | 199.956 | 9.373 | 2.834 | 1.856 | 1 |  |
| 6 | $1.37 \mathrm{E}-03$ | Adams- <br> Bashforth | 982.730 | 46.064 | 13.930 | 9.120 | 4.915 | 1 |

Table (4.10) and Figure (4.9) confirm the results we got in Example (4.1)
with one exception; Adams-Bashforth method has generated the greatest error instead of Milne's method.

Finally, we will compare these methods according to CPU time. We measured CPU time for these methods used in Example (4.2) with different step sizes and represented the results in Table (4.11). We found that the CPU time for the Taylor method is the highest, and that is due to the time cost of constructing Taylor expansion of $f(t, y(t))$. We noted also, that with decreasing step size the CPU time differences between Taylor method and other methods decreases in favor of Taylor method.

Table (4.11) Comparing CPU time

| Step size | RK <br> CPU time/s | Taylor <br> CPU time/s | Adams- <br> Moulton <br> CPU time/s | Predictor- <br> Corrector <br> CPU time/s | Milne <br> CPU time/s | Adams- <br> Bashforth <br> CPU time/s |

### 4.2 Error by Higher Order Taylor Methods

In this section, we will compare global error generated by different higher order Taylor methods (Taylor4, ...,Taylor10). We will see how error is reduced by increasing Taylor's order.

Table (4.11) contains errors accumulated after each step using Taylor methods $n=4, \ldots 10$. We plotted this data in Figure (4.10). Figure (4.10) contains the methods (a) for $n=4, \ldots 6$, (b) for $n=6, \ldots 8$ and (c) for $n=8, \ldots 10$. We intentionally repeated the method $n=6$ in (b) and the method $n=8$ in (c), to have better comparison.

Table (4.12): Global error generated by Taylor ( $\mathrm{n}=4, \ldots, 10$ ) methods

| $\mathrm{t}_{\mathrm{i}}$ | Taylor4 | Taylor5 | Taylor6 | Taylor7 | Taylor8 | Taylor9 | Taylor10 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0.5 | $0.000 \mathrm{E}+00$ | $0.000 \mathrm{E}+00$ | $0.000 \mathrm{E}+00$ | $0.000 \mathrm{E}+00$ | $0.000 \mathrm{E}+00$ | $0.000 \mathrm{E}+00$ | $0.000 \mathrm{E}+00$ |
| 0.6 | $1.881 \mathrm{E}-05$ | $1.188 \mathrm{E}-06$ | $1.881 \mathrm{E}-07$ | $1.188 \mathrm{E}-08$ | $1.881 \mathrm{E}-09$ | $1.188 \mathrm{E}-10$ | $1.881 \mathrm{E}-11$ |
| 0.7 | $2.682 \mathrm{E}-05$ | $3.179 \mathrm{E}-06$ | $2.273 \mathrm{E}-07$ | $3.248 \mathrm{E}-08$ | $1.854 \mathrm{E}-09$ | $3.232 \mathrm{E}-10$ | $1.442 \mathrm{E}-11$ |
| 0.8 | $2.228 \mathrm{E}-05$ | $4.810 \mathrm{E}-06$ | $1.167 \mathrm{E}-07$ | $4.421 \mathrm{E}-08$ | $2.971 \mathrm{E}-10$ | $3.790 \mathrm{E}-10$ | $3.108 \mathrm{E}-12$ |
| 0.9 | $9.768 \mathrm{E}-06$ | $5.356 \mathrm{E}-06$ | $3.884 \mathrm{E}-08$ | $4.104 \mathrm{E}-08$ | $1.056 \mathrm{E}-09$ | $2.780 \mathrm{E}-10$ | $1.087 \mathrm{E}-11$ |
| 1.0 | $4.070 \mathrm{E}-06$ | $4.882 \mathrm{E}-06$ | $1.432 \mathrm{E}-07$ | $2.994 \mathrm{E}-08$ | $1.341 \mathrm{E}-09$ | $1.628 \mathrm{E}-10$ | $6.638 \mathrm{E}-12$ |
| 1.1 | $1.454 \mathrm{E}-05$ | $3.897 \mathrm{E}-06$ | $1.708 \mathrm{E}-07$ | $1.966 \mathrm{E}-08$ | $9.182 \mathrm{E}-10$ | $1.120 \mathrm{E}-10$ | $5.711 \mathrm{E}-13$ |
| 1.2 | $2.011 \mathrm{E}-05$ | $2.885 \mathrm{E}-06$ | $1.469 \mathrm{E}-07$ | $1.380 \mathrm{E}-08$ | $4.060 \mathrm{E}-10$ | $1.098 \mathrm{E}-10$ | $1.982 \mathrm{E}-12$ |
| 1.3 | $2.147 \mathrm{E}-05$ | $2.096 \mathrm{E}-06$ | $1.056 \mathrm{E}-07$ | $1.163 \mathrm{E}-08$ | $9.640 \mathrm{E}-11$ | $1.193 \mathrm{E}-10$ | $1.796 \mathrm{E}-12$ |
| 1.4 | $2.014 \mathrm{E}-05$ | $1.574 \mathrm{E}-06$ | $6.816 \mathrm{E}-08$ | $1.124 \mathrm{E}-08$ | $1.170 \mathrm{E}-11$ | $1.221 \mathrm{E}-10$ | $8.697 \mathrm{E}-13$ |
| 1.5 | $1.751 \mathrm{E}-05$ | $1.266 \mathrm{E}-06$ | $4.195 \mathrm{E}-08$ | $1.126 \mathrm{E}-08$ | $1.164 \mathrm{E}-11$ | $1.166 \mathrm{E}-10$ | $1.859 \mathrm{E}-13$ |

Generally, the higher the Taylor's order, the better results we get. Exceptions are possible. We see that the results for $n=8$ are better than for $n=9$.

Figure (4.10) (a) Error propagation for Taylor Methods n=4,..., 6 for Example (4.2)

Figure (4.10): (b) Error propagation for Taylor Methods n=6,...,8 for Example (4.2)

Figure (4.10): (c) Error propagation for Taylor Methods n=8,...,10 for Example (4.2)

Finally, we can say that Taylor methods are a good choice to approximate the solution of initial value problem ordinary differential equations, since with algorithms we developed, all we need is to enter a higher value of $n$ to get more accurate solutions to a single first order IVP, a system of first order IVP's or a higher order IVP's.

### 4.3 Conclusions

The main aim of this thesis was to develop algorithms to get highly accurate approximations to the solution of initial value problem
$y^{\prime}(t)=f(t, y), a \leq t \leq b, y(a)=\alpha$,
and to study the concepts of stability and error propagation when a numerical method is applied to an initial value problem. Through our work, we found that higher order Taylor's methods give highly accurate approximations. However, the main obstacle was the tedious work of finding higher order derivatives of the initial value problem. We managed to write algorithms to find higher order derivatives of initial value problems and to construct Taylor's methods for solving these problems numerically. We also managed to develop these algorithms to deal in the same way with systems of first order initial value problems. In addition, we wrote an algorithm to convert higher order initial value problems into systems of first order initial value problems and to solve these systems. We translated all of these algorithms into Matlab programs. For these programs, all we need is to enter the problem, choose the desired order (n), and step size (h).

We wrote also algorithms, which we translated into Matlab programs for the fourth order Runge-Kutta, Adams-Bashforth, Adams-Moulton, Milne's and predictor-corrector (4-step fourth order Adams-Bashforth method as predictor and 3-step fourth order Adams-Moulton method as corrector) methods. We used these programs to compare errors generated by these methods and the fourth order Taylor's method. We found that single step methods (RungeKutta and Taylor) generated the best results. Since we can increase accuracy of Taylor's methods only by selecting a higher value of n , we concluded that with the programs we developed, higher order Taylor's methods could be a good choice for approximating the solution of initial value problems.

We used the test initial value problem (2.29)
$y^{\prime}(t)=\lambda y(t), \quad t>0, \quad y(0)=1, \quad \lambda \in \mathbb{C}$,
to study absolute stability of Taylor's methods. For this purpose, we wrote a Matlab program to find the error amplification functions and to plot the boundaries of stability regions of any Taylor's method.

To compare stability of Taylor's methods with other single step methods, we also wrote the Matlab Program (2.11) to find the error amplification functions and to plot the boundaries of stability regions of any explicit Runge-Kutta method. In addition, we wrote the Matlab Program (2.9) to plot the boundaries of stability regions of any explicit method given we have the error amplification functions. Matlab Program (2.10) plots the boundaries of
stability regions of implicit methods (only of orders less than five) given we have the error amplification functions.

Using results of these programs, we found that Taylor's methods, compared with other explicit methods, have similar stability regions. The most part of these stability regions lies at the imaginary axis and in the left part of the complex plane. That means, with enough small step size $h$ and with non positive real part of $\lambda$, Taylor' methods are stable.

Finally, we conclude that we can get higher accuracy of a wide range of initial value problems applying Taylor's methods to them.

## جامعة النجاح الوطنية

 كلية الدراسات العليا
# تحليل الأخطاء والثباتية للطرق العدديـة لحل مسائل القيم الابتدائية 

إعداد<br>عمـاد عمر فارس كايد<br>إشراف<br>أ. د. نـاجي قطناني

قـمت هذه الاطروحة استكمالا لمتطبات الحصول على درجة الماجستير في الرياضيات المحوسبة بكلية الاراسات العليا في جامعة النجاح الوطنية في نابلس، فلسطين.

# تحليل الأخطاء والثباتية للطرق العددية <br> لحل مسـائل القيم الابتدائية <br> إعداد <br> عمـاد عمر فارس كايد <br> إشراف <br> أ. د. نـاجي قطناني <br> الملخص 

مسائل القيم الابتدائية في معظمها هي ظواهر طبيعة كتبت بلغة الرياضيات. إن حل مسائل القيم
الابتدائية هو أحد اكثر حقول الرياضيات تحديا بسبب الرغبة المستمرة لللاقة عند علماء الرياضيات.
يركز هذا العمل بشكل أساسي على تطوير خوارزميات وبرامج لنكوين طرق تيلر العليا لتقريب حل مسائل القيم الابتدائية من الارجة الاولى ولتقريب حل انظمة مسائل القيم الابتدائية من الارجة الاولى ولتقريب حل مسائل القيم الابتدائية من الارجات العليا. بالاضافة إلى ذلك يركز هذا العمل على دراسة الأخطاء والثباتية للطرق العددية لحل مسائل القيم الابتدائئة. ولهذا الغرض قمنا بتطوير برامج لايجاد اقترانات تكبير الاخطاء لطرق تيلر وطرق رنجي-كتا الصريحة ولرسم حدود مناطق الثباتية
لهذه الطرق وطرق أخرى.

لقد استتنجنا انه وباستخدام البر امج التي طورناها يوكن أن تكون طرق تيلر العليا خيارا جيدا لتقريب حول مجمو عة واسعة من مسائل القيم الابتدائية.
