## The Topology of Spaces of Polygons

#### Abstract

We study the topology of spaces of polygons in Euclidean space, viewed up to translations. The main results concern the structure of the homology groups and of the cohomology rings of the spaces. In particular, it is shown that the spaces are classified by their $\mathbf{Z}_{2}$-cohomology rings. A principal tool used in the proofs is a new lacunary principle for Morse-Bott functions, which may be of independent interest. Several applications are discussed.

## Declaration

This thesis is based on research carried out in the Pure Mathematics Group at the Department of Mathematical Sciences, Durham University. No part of this thesis has been submitted elsewhere for any other degree or qualification.

Some of the material is based on contributions to joint research with Professor Michael Farber. These results can be found in the articles [9] and [10] as well as in the preprint [11], submitted for publication. Most of the results of Chapter 3 and the material in the appendix are independent research and appear here for the first time.

## Copyright © 2011 by Viktor Fromm.

The copyright of this thesis rests with the author. No quotations from it should be published without the author's prior written consent and information derived from it should be acknowledged.

## Acknowledgements

I would like to express my deep gratitude to Professor Michael Farber for his invaluable support and advice. His encouragement and enthusiasm guided me throughout my studies and without them this work would have not been possible.

I am grateful for financial support provided through the Durham Doctoral Fellowship.

I would like to thank my parents for their constant encouragement and support.

## Chapter 0

## Introduction

Spaces of polygons in Euclidean space $\mathbb{R}^{d}$ are particularly well-understood in the cases of dimensions $d=2$ and $d=3$. Most of the known results revolve around the configuration spaces defined by considering polygons up to the action of the full group of orientation-preserving Euclidean isometries. In the planar case $d=2$ these spaces are often denoted by $M_{\ell}$ whereas for $d=3$ the symbol $N_{\ell}$ is used. Here $\ell=\left(l_{1}, \ldots, l_{n}\right)$ is the tuple whose entries are the lengths of the edges of the polygon. These lengths are assumed fixed and their choice determines the topology of the spaces $M_{\ell}$ and $N_{\ell}$.

The investigation of the spaces $M_{\ell}$ and $N_{\ell}$ commenced as part of the study of the topology of configuration spaces of linkages, initiated by W. Thurston and his collaborators ([39]). This investigation was continued in the work of J.-Cl. Hausmann in [20] and of M. Kapovich and J. Millson in [27]. Results on the topology of equilateral polygon spaces were obtained by Y. Kamiyama and his collaborators (see e.g. [25],[26]).

In [40, K. Walker studied the planar polygon spaces $M_{\ell}$, stating a description of the homology groups and a conjecture on the structure of the cohomology rings. A rigorous computation of the homology groups of $M_{\ell}$ was given by M. Farber and D. Schuetz in [15]. Walker's conjectural statement was established under an additional
assumption by M. Farber, J.-Cl. Hausmann and D. Schuetz ([12]). This assumption was removed in later work of D. Schuetz ([36]), establishing the full statement of the conjecture.

The homology groups of the spaces $N_{\ell}$ of spatial polygons were computed by A. A. Klyachko in [30]. In [22], A. Knutson and J.-Cl. Hausmann used the theory of toric varieties to determine the cohomology ring of $N_{\ell}$. An analogue of Walker's conjecture for the spaces $N_{\ell}$ was proved in [12].

In this thesis, polygon spaces are studied from a different point of view: we consider polygons up to translations. We denote these free polygon spaces by $E_{d}(\ell)$. Our study of these spaces is motivated by the fact that while the direct analogues of $M_{\ell}$ and $N_{\ell}$ in dimensions $d>3$ are singular, the spaces $E_{d}(\ell)$ are generically manifolds in all dimensions (see Proposition 1.5 .3 below).

Chapter 1 is devoted to the discussion of the basic properties of the spaces $E_{d}(\ell)$. Analogously to the cases of the spaces $M_{\ell}$ and $N_{\ell}$, there is a close relationship between the topology of $E_{d}(\ell)$ and combinatorial properties of the length vector $\ell$. In Section 1.3, we recall the combinatorial classification of length vectors in the language of short, long and median sets.

In order to be able to test general results, it is useful to have at one's disposal some cases where the space $E_{d}(\ell)$ can be determined explicitly. Results of this type are given in Section 1.6 (see also Section 1.2). In Section 1.6 , we also introduce and study the robot arm distance map. In our setting, this map is a Morse-Bott function with rather special properties (Lemma 1.6.1).

The main tool behind our results on the homology and the cohomology of the spaces $E_{d}(\ell)$ is a certain Morse-Bott analogue of the classical Morse lacunary principle. This analogue, which may be of independent interest, is established in Chapter 2 it is applied in Chapter 3 to study the homology groups of the spaces $E_{d}(\ell)$. The main
results are as follows. The $\mathbf{Z}_{2}$-Betti numbers of the spaces are computed explicitly (Theorem 3.1.1). It is shown that the integral homology groups are torsion-free if $d$ is even; in the case where $d$ is odd, an explicit combinatorial criterion for the existence of torsion elements is found (Theorems 3.1.2, 3.1.3 and 3.1.5). These results complement the previous work of M. Farber and D. Schuetz on the planar case ([15]). Sections 3.2 and 3.3 contain applications and the discussion of several special cases.

In Section 3.4, we pursue the probabilistic approach to the topology of the spaces $E_{d}(\ell)$ : the length vector $\ell$ is viewed as a random variable and topological invariants of the space $E_{d}(\ell)$ as random functions. This study is motivated by the idea that in applications the numbers $l_{j}$ may not be known precisely, but rather different edge lengths arise with different probability. The main results of Section 3.4, Theorems 3.4.1 and 3.4.2, describe the asymptotic behaviour of the homotopy groups and of the Betti numbers of the spaces $E_{d}(\ell)$ as the number $n$ of edges becomes large. These results are inspired by the work of M. Farber and T. Kappeler in [14] and of M. Farber in [8].

Chapter 4 is concerned with the study of polygonal linkages in the case where the lengths of all the segments except one are fixed and the length of the remaining segment varies in a prescribed interval. Configuration spaces of this type describe mechanisms with a prismatic joint. The main result of Chapter 4 is the computation of the homology groups of these spaces in the planar case. In Section 4.3, we discuss an application motivated by the so-called Topological Hypothesis from the theory of phase transitions.

While the results of Chapter 3 describe the dependence of the homology groups of the spaces $E_{d}(\ell)$ on the combinatorial properties of the length vector $\ell$, the purpose of Chapter 5 is the investigation of the inverse problem. Namely, we study the question whether knowledge of the topology of the space $E_{d}(\ell)$ is sufficient to determine the length vector $\ell$. One of the main results of this thesis, Theorem 5.1.1,
states that the graded isomorphism type of the $\mathbf{Z}_{2}$-cohomology ring $H^{*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ determines $\ell$ up to a combinatorially defined notion of equivalence. This theorem establishes an analogue of Walker's conjecture in all dimensions $d>2$ and complements the results of [12]. Its proof uses the techniques introduced in [12], with the Morse-Bott lacunary principle of Chapter 2 as a central additional tool.

In a separate appendix we discuss the relationship of the spaces $E_{d}(\ell)$ to configuration spaces of polygonal chains that were studied in [20] and in [21]. The material of the appendix is motivated by the results in the recent paper [13] and the questions raised therein.

## Chapter 1

## Spaces of Polygons

In this chapter we discuss basic properties of the spaces of polygons in Euclidean space. We study smoothness of the spaces and determine them explicitly in several special cases. Much of the material of this chapter is expository and similar to previously known results.

### 1.1 Spaces of Polygons in Euclidean Space

The objective of this thesis is the study of the topology of spaces of polygons in Euclidean space. Throughout, we will denote by $n \geq 3$ the number of edges of the polygon and by $d \geq 2$ the dimension of the ambient Euclidean space.

A polygon whose edges have length $l_{1}, \ldots, l_{n}>0$ is defined by specifying an $n$-tuple $P_{1}, \ldots, P_{n}$ of points in $\mathbb{R}^{d}$, so that for each $j=1, \ldots, n-1$ the vector $P_{j+1}-P_{j}$ has length $l_{j}$ and the vector $P_{1}-P_{n}$ has length $l_{n}$. We will identify two polygons whenever one is obtained from the other by a translation.

The unit vectors in the directions $P_{j+1}-P_{j}, j=1, \ldots, n-1$ and $P_{1}-P_{n}$ determine the tuple $\left(P_{1}, \ldots, P_{n}\right)$ uniquely up to translations. Thus formally, the space of polygons may be defined as follows.

Definition 1.1.1. Let $\ell=\left(l_{1}, \ldots, l_{n}\right) \in \mathbb{R}_{>0}^{n}$ be an $n$-tuple of positive real numbers.

Denote $W=\left(S^{d-1}\right)^{n}$. We define the space of polygons in $\mathbb{R}^{d}$ on $n$ edges of length $l_{1}, \ldots, l_{n}$, viewed up to translations, as the subset $E_{d}(\ell) \subset W$ given by

$$
E_{d}(\ell)=\left\{\left(u_{1}, \ldots, u_{n}\right) \in W: \sum_{j=1}^{n} l_{j} u_{j}=0\right\}
$$

equipped with the subspace topology.

One also refers to $E_{d}(\ell)$ as the free polygon space (in contrast to configuration spaces defined by viewing polygons up to all orientation-preserving Euclidean isometries).

The homeomorphism type of the space $E_{d}(\ell)$ depends on the choice of the edge lengths $l_{1}, \ldots, l_{n}$. We will refer to the tuple $\ell=\left(l_{1}, \ldots, l_{n}\right)$ as a length vector.

As is made more precise below, by varying the length of one of the edges in some interval, one obtains a cobordism between spaces $E_{d}(\ell)$ for different length vectors $\ell$. Formally, such cobordisms are defined as follows.

Let

$$
\ell^{-}=\left(l_{1}^{-}, \ldots, l_{n}^{-}\right)
$$

and

$$
\ell^{+}=\left(l_{1}^{+}, \ldots, l_{n}^{+}\right)
$$

be two length vectors so that

$$
l_{j}^{-}=l_{j}^{+} \text {for } j=1, \ldots, n-1 \text { and } l_{n}^{-}<l_{n}^{+}
$$

Denote by $A \subset \mathbb{R}^{n}$ the interval connecting $\ell^{-}$and $\ell^{+}$:

$$
A=\left\{\left(l_{1}, \ldots, l_{n}\right) \in \mathbb{R}^{n}: l_{j}^{-} \leq l_{j} \leq l_{j}^{+}, j=1, \ldots, n\right\} .
$$

Definition 1.1.2. For $A \subset \mathbb{R}^{n}$ as above, we define the space $E_{d}(A)$ as the subset $E_{d}(A) \subset W$ given by

$$
E_{d}(A)=\bigcup_{\ell \in A} E_{d}(\ell)
$$

equipped with the subspace topology.

Figure 1.1: A planar polygonal linkage with a prismatic joint.

We can view $E_{d}(A)$ as the configuration space of a polygonal linkage, where the lengths of all the segments except one are fixed and the remaining segment is telescopic: its length varies in a prescribed interval. A segment of this type is sometimes also called a prismatic joint ([33]). We will refer to $A$ as the metric data of the telescopic linkage.

### 1.2 The Case of a small Number of Edges

This section is of mostly expository nature and similar to the material in the first Chapter of [7]. We employ elementary geometric considerations to study the space $E_{d}(\ell)$ in some simple cases. This approach is useful for illustrating the dependence of the topology of $E_{d}(\ell)$ on the choice of the length vector $\ell$.

Throughout this section, we shall assume that the entries of $\ell$ are ordered according to their size:

$$
\begin{equation*}
l_{1} \leq l_{2} \leq \cdots \leq l_{n} \tag{1.1}
\end{equation*}
$$

We view $W=\left(S^{d-1}\right)^{n}$ as the configuration space of a robot arm in $\mathbb{R}^{d}$, a mechanism consisting of $n$ segments connected by revolving joints into a single polygonal chain whose initial point, also referred to as the grip, is fixed at the origin. An element $\left(u_{1}, \ldots, u_{n}\right) \in W$ corresponds to the configuration where for $j=1, \ldots, n, u_{j} \in S^{d-1}$ is the direction of the $j$ th segment of the robot arm.

Figure 1.2: A robot arm with four segments.

Denote by

$$
\alpha: W \rightarrow \mathbb{R}^{d}
$$

the map which associates to every configuration of the robot arm the position of the endpoint. Explicitly, if $l_{1}, \ldots, l_{n}$ are the lengths of the individual segments of the robot arm, then the map $\alpha$ is given by

$$
\alpha\left(u_{1}, \ldots, u_{n}\right)=\sum_{j=1}^{n} l_{j} u_{j} .
$$

The map $\alpha$ is called the workspace map and its image the workspace of the robot arm. In the case $n=1$, the workspace is a sphere in $\mathbb{R}^{d}$. For $n \geq 2$ the workspace is a closed spherical shell $A \subset \mathbb{R}^{d}$ centred at the origin, with outer radius $r_{+}=l_{1}+\cdots+l_{n}$ and inner radius $r_{-}=\max \left\{l_{n}-\left(l_{1}+\cdots+l_{n-1}\right), 0\right\}$. In particular, in the case of a robot arm with two segments of length $l_{1}<l_{2}$, the workspace is a spherical shell with outer radius $l_{1}+l_{2}$ and inner radius $l_{2}-l_{1}$.

The following lemma summarises some basic properties of the workspace map.

Lemma 1.2.1. Consider a robot arm with two segments of length $l_{1}<l_{2}$, workspace map $\alpha: W=\left(S^{d-1}\right)^{2} \rightarrow \mathbb{R}^{d}$ and workspace $A=\alpha(W)$.

1. For every interior point $p$ of $A$ the preimage $\alpha^{-1}(p)$ is homeomorphic to the sphere $S^{d-2}$. In particular, in the case $d=2$ the preimage consists of two points.
2. If $p$ is a boundary point of $A$, then the preimage $\alpha^{-1}(p)$ consists of a single point.
3. Let $S \subset \mathbb{R}^{d}$ be a sphere of radius $r$ centred at the origin. If

$$
l_{2}-l_{1}<r<l_{1}+l_{2},
$$

then the preimage $\alpha^{-1}(S)$ is homeomorphic to $T^{1} S^{d-1}$, the total space of the unit tangent bundle of the sphere $S^{d-1}$.

For $d=2$, the space $T^{1} S^{d-1}$ is a disjoint union of two copies of $S^{1}$.

Let us consider the space $E_{d}(\ell)$ for $n=3$. We identify elements of $E_{d}(\ell)$ with configurations of a robot arm with two segments of length $l_{1}$ and $l_{2}$, so that the endpoint of the arm lies on a circle $S$ of radius $l_{3}$ about the origin. Thus in the case $n=3$ the subset $E_{d}(\ell) \subset\left(S^{d-1}\right)^{3}$ coincides with the preimage $\alpha^{-1}(S)$.

If $l_{3}>l_{1}+l_{2}$, then $S$ is disjoint from the workspace of the arm and hence in this case $E_{d}(\ell)=\emptyset$. If $l_{3}<l_{1}+l_{2}$, then using the third part of Lemma 1.2.1, one finds a homeomorphism

$$
E_{d}(\ell) \simeq T^{1} S^{d-1}
$$

We now study the case $n=4, d=2$. Here elements of the space $E_{2}(\ell)$ are quadrangles in the plane, viewed up to translations. Using cyclic notation, we label for $j=1,2,3,4$ by $P_{j}$ the vertex of the quadrangle which is adjacent to the edges $l_{j-1}$ and $l_{j}$. As two polygons that are obtained from each other by a translation are identified, it may be assumed that one of the vertices $P_{j}$ lies at some fixed point in $\mathbb{R}^{d}$. We will assume that the vertex $P_{2}$ adjacent to the edges $l_{1}$ and $l_{2}$ is fixed at the origin.

The geometric locus of the possible positions of the vertex $P_{4}$ is the intersection of two annuli $A=A\left(\rho_{1}, \rho_{2}\right)$ and $A^{\prime}=A^{\prime}\left(\rho_{1}^{\prime}, \rho_{2}^{\prime}\right)$ centred at the origin, with inner and outer radii given respectively by

$$
\rho_{1}=l_{3}-l_{2}, \rho_{2}=l_{3}+l_{2}
$$

and by

$$
\rho_{1}^{\prime}=l_{4}-l_{1}, \quad \rho_{2}^{\prime}=l_{4}+l_{1} .
$$

Figure 1.3: The locus of possible positions of the point $P_{4}$ as an intersection of workspaces.

If $l_{4}>l_{1}+l_{2}+l_{3}$, then $A$ and $A^{\prime}$ are disjoint and hence $E_{2}(\ell)=\emptyset$.

Next, we assume that $l_{4}<l_{1}+l_{2}+l_{3}$ and thus the intersection $A \cap A^{\prime}$ is non-empty. For every interior point $P$ of $A \cap A^{\prime}$, there are four pairwise distinct quadrangles so that the vertex $P_{4}$ lies at $P$. These four quadrangles are obtained from each other by reflecting the positions of the vertices $P_{1}$ and $P_{3}$ on the line connecting the origin to $P_{4}$. There are two distinct quadrangles so that the vertex $P_{4}$ lies at a given boundary point of the intersection $A \cap A^{\prime}$ : in this case either the vertex $P_{1}$ or the vertex $P_{2}$ lies on the line connecting the origin with $P_{4}$.

We see that the space $E_{2}(\ell)$ is obtained from the disjoint union of four annuli by an identification of boundary components. Since $\ell$ is ordered,

$$
l_{4}-l_{1}>l_{3}-l_{2}
$$

and hence on the inner boundary of $A \cap A^{\prime}$, the edges $l_{1}$ and $l_{4}$ are collinear.

If

$$
l_{2}+l_{3}>l_{1}+l_{4}
$$

then on the outer boundary of $A \cap A^{\prime}$, the edges $l_{1}$ and $l_{4}$ are collinear as well. Thus in this case the annuli are glued together as indicated by Figure 1.4 .

Figure 1.4: The space $E_{2}(\ell)$ in the case $n=4$ and $l_{2}+l_{3}>l_{1}+l_{4}$.

In the case

$$
l_{2}+l_{3}<l_{1}+l_{4}
$$

the edges $l_{2}$ and $l_{3}$ are collinear on the outer boundary of $A \cap A^{\prime}$ and the identification is as in Figure 1.5.

Figure 1.5: The space $E_{2}(\ell)$ for $n=4$ and $l_{4}-l_{1}<l_{2}+l_{3}<l_{1}+l_{4}$.

We conclude that if $l_{2}+l_{3}>l_{1}+l_{4}$, then

$$
E_{2}(\ell) \simeq T^{2} \cup T^{2}
$$

whereas for $l_{4}-l_{1}<l_{2}+l_{3}<l_{1}+l_{4}$,

$$
E_{2}(\ell) \simeq T^{2}
$$

The following proposition summarises the above results:
Proposition 1.2.2. Let $\ell$ be a length vector with $l_{1} \leq l_{2} \leq \cdots \leq l_{n}$.

1. Let $n=3$. If $l_{3}>l_{1}+l_{2}$, then

$$
E_{d}(\ell)=\emptyset,
$$

whereas for $l_{3}<l_{1}+l_{2}$, there is a homeomorphism

$$
E_{d}(\ell) \simeq T^{1} S^{d-1}
$$

2. Let $n=4$ and $d=2$. If $l_{4}>l_{1}+l_{2}+l_{3}$, then the space $E_{d}(\ell)$ is empty.

Assume that $l_{4}<l_{1}+l_{2}+l_{3}$. If $l_{2}+l_{3}>l_{1}+l_{4}$, then $E_{2}(\ell)$ is a disjoint union of two tori:

$$
E_{2}(\ell) \simeq T^{2} \cup T^{2}
$$

whereas for $l_{2}+l_{3}<l_{1}+l_{4}$, there is a homeomorphism

$$
E_{2}(\ell) \simeq T^{2}
$$

While similar arguments can be applied to analyze the case $n=4, d>2$, it will be more convenient to study this case using different methods that are discussed further below. The proof of the following result is given in Section 1.6 .

Proposition 1.2.3. Let $n=4$ and assume that $l_{1} \leq l_{2} \leq l_{3} \leq l_{4}$ and $l_{4}<l_{1}+l_{2}+l_{3}$.

1. If $l_{2}+l_{3}>l_{1}+l_{4}$, then there is a homeomorphism

$$
E_{d}(\ell) \simeq S^{d-1} \times T^{1} S^{d-1}
$$

2. In the case $l_{2}+l_{3}<l_{1}+l_{4}$ the space $E_{d}(\ell)$ is given by

$$
E_{d}(\ell) \simeq S^{2(d-1)-1} \times S^{d-1}
$$

Since for $d=2$, the space $T^{1} S^{d-1}$ is a disjoint union of two copies of $S^{1}$, in this case the claim of Proposition 1.2 .3 follows from the second assertion of Proposition 1.2.2.

### 1.3 Combinatorics of Length Vectors

As illustrated by the discussion in the previous section, there is a close relationship between the topology of the spaces $E_{d}(\ell)$ and the combinatorial properties of the length vector $\ell$. The purpose of this section is to recall the classification of length vectors in the language of short, long and median sets.

A length vector $\ell$ is called ordered if the inequalities

$$
l_{1} \leq \cdots \leq l_{n}
$$

hold. We call $\ell$ generic if there is no choice of $\epsilon_{j}= \pm 1$ for $j=1, \ldots, n$ so that

$$
\sum_{j=1}^{n} \epsilon_{j} l_{j}=0
$$

A subset $J \subset\{1, \ldots, n\}$ is called long (respectively short or median) with respect to $\ell$ if

$$
\ell_{J}=\sum_{j \in J} l_{j}-\sum_{j \notin J} l_{j}>0
$$

(respectively. $\ell_{J}<0$ or $\ell_{J}=0$ ). A length vector $\ell$ is generic if and only if no subset $J \subset\{1, \ldots, n\}$ is median with respect to $\ell$. The complement

$$
\bar{J}=\{1, \ldots, n\}-J
$$

of a long set $J$ is a short set.

We write $\mathcal{L}(\ell)$ (respectively $\mathcal{S}(\ell), \mathcal{M}(\ell))$ for the set of all subsets of $\{1, \ldots, n\}$ that are long (respectively short, median) with respect to $\ell$. Denote by $\mathcal{L}_{n}(\ell) \subset \mathcal{L}(\ell)$ (respectively $\left.\mathcal{S}_{n}(\ell) \subset \mathcal{S}(\ell), \mathcal{M}_{n}(\ell) \subset \mathcal{M}(\ell)\right)$ those long sets (respectively. short, median sets) which contain the index $n$.

Definition 1.3.1. Let $\ell, \ell^{\prime}$ be two length vectors. We say that $\ell$ and $\ell^{\prime}$ lie in the same stratum if the sets $\mathcal{L}(\ell)$ and $\mathcal{L}\left(\ell^{\prime}\right)$ coincide. If, in addition, both $\ell$ and $\ell^{\prime}$ are generic, then we say that $\ell$ and $\ell^{\prime}$ lie in the same chamber.

The geometric meaning of these notions is as follows. For every subset $J \subset\{1, \ldots, n\}$, consider the hyperplane $H_{J} \subset \mathbb{R}^{n}$ defined by

$$
H_{J}=\left\{\left(x_{1}, \ldots, x_{n}\right) \in \mathbb{R}^{n}: \sum_{j \in J} x_{j}-\sum_{j \notin J} x_{j}=0\right\},
$$

also referred to as the wall corresponding to $J$. Since every subset $J \subset\{1, \ldots, n\}$ defines the same wall as its complement, there are $2^{n-1}$ distinct walls. For $J=\emptyset$ and $J=\{1, \ldots, n\}$, the hyperplane $H_{J} \subset \mathbb{R}^{n}$ is disjoint from $\mathbb{R}_{>0}^{n}$.

A length vector $\ell \in \mathbb{R}_{>0}^{n}$ is generic if and only if $\ell$ does not lie on a wall. The walls define a stratification of $\mathbb{R}_{>0}^{n}$ : for every $k \geq 0$ the codimension $k$ strata are the connected components of the subset consisting of those points of $\mathbb{R}_{>0}^{n}$, which lie on exactly $k$ distinct walls. The codimension zero strata are the chambers. Two generic length vectors lie in the same chamber if and only if they lie in the same connected component of the complement $\mathbb{R}_{>0}^{n}-\cup_{J} H_{J}$ of the union of all the walls.

The following observation is well-known (Lemma 4 in [12], see also Proposition 2.5 in [22]):

Proposition 1.3.2. Two length vectors $\ell$ and $\ell^{\prime}$ lie in the same stratum if and only if the sets $\mathcal{L}_{n}(\ell)$ and $\mathcal{S}_{n}(\ell)$ coincide with $\mathcal{L}_{n}\left(\ell^{\prime}\right)$ and $\mathcal{S}_{n}\left(\ell^{\prime}\right)$ correspondingly.

If $\ell$ is generic, then a subset $J \subset\{1, \ldots, n\}$ with $n \in J$ is an element of $\mathcal{S}_{n}(\ell)$ if and only if $J \notin \mathcal{L}_{n}(\ell)$. Thus Proposition 1.3 .2 implies:

Corollary 1.3.3. Two generic length vectors $\ell$ and $\ell^{\prime}$ lie in the same chamber if and only if the sets $\mathcal{L}_{n}(\ell)$ and $\mathcal{L}_{n}\left(\ell^{\prime}\right)$ coincide.

The following result is useful in understanding how the stratum of an ordered length vector changes when one permutes the entries of the length vector.

Lemma 1.3.4. Let $\ell, \ell^{\prime}$ be two ordered length vectors.

1. If there exists a permutation $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ so that $\sigma(n)=n$ and the sets $\sigma\left(\mathcal{L}_{n}(\ell)\right)$ and $\mathcal{L}_{n}\left(\ell^{\prime}\right)$ coincide, then the sets $\mathcal{L}_{n}(\ell)$ and $\mathcal{L}_{n}\left(\ell^{\prime}\right)$ coincide
as well. Similarly, if $\sigma(n)=n$ and the sets $\sigma\left(\mathcal{S}_{n}(\ell)\right)$ and $\mathcal{S}_{n}\left(\ell^{\prime}\right)$ coincide, then so do the sets $\mathcal{S}_{n}(\ell)$ and $\mathcal{S}_{n}\left(\ell^{\prime}\right)$.
2. For a permutation $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$, denote by $\sigma(\ell)$ the length vector obtained by interchanging the entries of $\ell$ by $\sigma$. If the length vectors $\sigma(\ell)$ and $\ell^{\prime}$ lie in the same stratum, then so do $\ell$ and $\ell^{\prime}$.

Proof. The first assertion can be found as Lemma 3 in [12]. The proof given in [12] also shows that if $\ell$ and $\ell^{\prime}$ are ordered and $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ is an arbitrary permutation so that the sets $\sigma(\mathcal{L}(\ell))$ and $\mathcal{L}\left(\ell^{\prime}\right)$ coincide, then the sets $\mathcal{L}(\ell)$ and $\mathcal{L}\left(\ell^{\prime}\right)$ coincide as well. Since $\sigma(\mathcal{L}(\ell))=\mathcal{L}(\sigma(\ell))$, this proves the second assertion.

If we vary an entry of a generic length vector in a sufficiently small interval, we obtain length vectors that lie in the same chamber. To make this statement precise, it is useful to consider for a given length vector $\ell$ the quantity

$$
[\ell]=\min \left(\sum_{j=1}^{n} \epsilon_{j} l_{j}\right),
$$

where the minimum is taken over all choices of $\epsilon_{j} \in\{ \pm 1\}, j=1, \ldots, n$, so that

$$
\sum_{j=1}^{n} \epsilon_{j} l_{j}>0 .
$$

Proposition 1.3.5. Let $\ell$ be a length vector and let $0<\varepsilon<\min \left(l_{n},[\ell]\right)$. Then

$$
\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}-\varepsilon\right)
$$

and

$$
\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}+\varepsilon\right)
$$

are both generic. Moreover, if $\ell$ is generic, then the length vectors $\ell, \ell^{-}$and $\ell^{+}$all lie in the same chamber.

Proof. The first assertion readily follows from the definition of the quantity $[\ell]$. If $\ell$ is generic, then a subset $J \subset\{1, \ldots, n\}$ with $n \in J$ is long with respect to $\ell^{+}$if and only if it is long with respect to $\ell$. Thus the sets $\mathcal{L}_{n}(\ell)$ and $\mathcal{L}_{n}\left(\ell^{+}\right)$coincide; analogously so do the sets $\mathcal{L}_{n}(\ell)$ and $\mathcal{L}_{n}\left(\ell^{-}\right)$. It follows from Corollary 1.3.3 that in this case $\ell, \ell^{-}$and $\ell^{+}$lie in the same chamber.

One concludes from the definition of the quantity $[\ell]$ that if $0<\varepsilon<[\ell]$, then every length vector obtained from $\ell$ by inserting $\varepsilon$ as a new entry is generic. The following Lemma, first proved in [23], will be important for the results of Chapter 5 .

Lemma 1.3.6 ([23], Lemma 5.1). Let $\ell, \ell^{\prime}$ be two length vectors and suppose that $0<\varepsilon<[\ell]$ and $0<\varepsilon^{\prime}<\left[\ell^{\prime}\right]$. Denote by $(\varepsilon, \ell)$ the length vector obtained from $\ell$ by inserting $\varepsilon$ as the new first entry. If $(\varepsilon, \ell)$ and $\left(\varepsilon^{\prime}, \ell^{\prime}\right)$ lie in the same chamber, then $\ell$ and $\ell^{\prime}$ lie in the same stratum.

Proof. For every subset $J \subset\{1, \ldots, n\}$, denote by $\widetilde{J} \subset\{2, \ldots, n+1\}$ the set $\widetilde{J}=\{j+1: j \in J\}$. Using the definition of the quantity $[\ell]$, one concludes that the map $J \mapsto \widetilde{J}$ defines a bijection between $\mathcal{L}(\ell)$ and

$$
\{J \in \mathcal{L}(\varepsilon, \ell): 1 \notin J\}
$$

Thus if the two sets $\mathcal{L}(\varepsilon, \ell)$ and $\mathcal{L}\left(\varepsilon^{\prime}, \ell^{\prime}\right)$ coincide, then so do the two sets $\mathcal{L}(\ell)$ and $\mathcal{L}\left(\ell^{\prime}\right)$.

### 1.4 Counting short and median Sets

In this section we define several numerical quantities based on counts of subsets of the index set $\{1, \ldots, n\}$ that are short or median with respect to a given length vector. These numerical quantities will be used in the subsequent study of the Betti numbers of the spaces introduced in Section 1.1 .

Definition 1.4.1. Let $\ell$ be a length vector and let $m \in\{1, \ldots, n\}$ be the index of any maximal entry of the length vector $\ell$. For $k=0, \ldots, n-1$, we define numbers $a_{k}(\ell), b_{k}(\ell)$ and $\alpha_{k}(\ell)$ as follows:

1. We define $a_{k}(\ell)$ (respectively $b_{k}(\ell)$ ) as the number of subsets $J \subset\{1, \ldots, n\}$ so that $m \in J,|J|=k+1$ and $J$ is short (respectively median) with respect to $\ell$.
2. We denote by $\alpha_{k}(\ell)$ the number of subsets $J \subset\{1, \ldots, n\}$ of cardinality $|J|=$ $k+1$ which contain the index $n$ and are short with respect to $\ell$.

It will be convenient to extend this Definition to the case $k=-1$ by defining $a_{-1}(\ell)=b_{-1}(l)=\alpha_{-1}(\ell)=0$ for every length vector $\ell$.

The difference between the numbers $a_{k}(\ell)$ and $\alpha_{k}(\ell)$ is that while the first is the number of short sets which contain the index of a maximal entry of $\ell$, the second is the number of short sets containing the index $n$. If $n$ is the index of a maximal entry of $\ell$, then $a_{k}(\ell)$ and $\alpha_{k}(\ell)$ coincide for all $k$.

The proposition below summarises some properties of the numbers $a_{k}(\ell), b_{k}(\ell)$ and $\alpha_{k}(\ell)$ that are readily concluded from their Definition:

Proposition 1.4.2. 1. A length vector $\ell$ is generic if and only if all the numbers $b_{k}(\ell)$ vanish.
2. If the length vector $\ell^{\prime}$ is obtained from $\ell$ by a permutation of the entries, then the numbers $a_{k}(\ell)$ and $a_{k}\left(\ell^{\prime}\right)$ coincide for all $k$. If $\ell^{\prime}$ is obtained from $\ell$ by a permutation which fixes the last entry, then $\alpha_{k}(\ell)=\alpha_{k}\left(\ell^{\prime}\right)$ for all $k$.

The following numbers play an important role in the study of the homology of spaces of polygons with a telescopic edge.

Definition 1.4.3. Let $\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{-}\right)$and $\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{+}\right)$be two length vectors with

$$
l_{1} \leq \cdots \leq l_{n-1}
$$

For $k=0, \ldots, n-1$, we define $\beta_{k}\left(\ell^{+}, \ell^{-}\right)$to be the number of subsets $J \subset\{1, \ldots, n\}$ which satisfy the following conditions:

1. $|J|=k+1$.
2. $n \in J$ and $n-1 \notin J$.
3. $J$ is short with respect to $\ell^{-}$.
4. The subset $J^{\prime}=J-\{n\} \cup\{n-1\}$ is long with respect to $\ell^{+}$.

It will also be useful to extend this definition to the case $k=-1$ by setting $\beta_{-1}\left(\ell^{+}, \ell^{-}\right)=0$ for all $\ell^{+}, \ell^{-}$.

The next proposition describes the basic properties of the numbers $\beta_{k}$.
Proposition 1.4.4. 1. For $k=0, \ldots, n-2$,

$$
\beta_{k}\left(\ell^{-}, \ell^{+}\right)=\beta_{n-k-2}\left(\ell^{+}, \ell^{-}\right)
$$

2. If

$$
l_{n}^{-}+l_{n}^{+} \geq 2 l_{n-1}
$$

then $\beta_{k}\left(\ell^{+}, \ell^{-}\right)=0$ for all $k$.
3. Let $\ell$ be generic and let

$$
\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}-\varepsilon\right)
$$

and

$$
\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}+\varepsilon\right),
$$

where $0<\varepsilon<\min \left(l_{n},[\ell]\right)$. Then

$$
\beta_{k}\left(\ell^{+}, \ell^{-}\right)=\alpha_{k}(\ell)-a_{k}(\ell) .
$$

Proof. If a subset $J \subset\{1, \ldots, n\}$ satisfies the four conditions of Definition 1.4.3, then the set

$$
I=\bar{J} \cup\{n\}-\{n-1\}
$$

satisfies conditions 2,3 and 4 of this Definition, with the roles of $\ell^{-}$and $\ell^{+}$interchanged. Here $\bar{J}$ denotes the complement of $J$ in $\{1, \ldots, n\}$. If $|J|=k+1$, then the cardinality of the set $I$ is

$$
|I|=n-k-1=(n-k-2)+1 .
$$

We conclude that $\beta_{k}\left(\ell^{-}, \ell^{+}\right)=\beta_{n-k-2}\left(\ell^{+}, \ell^{-}\right)$.

To prove the second claim, let $J \subset\{1, \ldots, n\}$ be a subset satisfying the first three
conditions of Definition 1.4.3. Consider the set $J^{\prime}=J-\{n\} \cup\{n-1\}$. The quantity $\ell_{J^{\prime}}^{+}$can be expressed as

$$
\ell_{J^{\prime}}^{+}=\ell_{J}^{+}-2 l_{n}^{+}+2 l_{n-1}=\ell_{J}^{-}-\left(l_{n}^{-}+l_{n}^{+}\right)+2 l_{n-1} .
$$

Thus if $l_{n}^{-}+l_{n}^{+} \geq 2 l_{n-1}$, then the inequality

$$
\ell_{J^{\prime}}^{+} \leq \ell_{J}^{-} \leq 0
$$

holds and the fourth condition of Definition 1.4.3 is violated. We see that if $l_{n}^{-}+l_{n}^{+} \geq 2 l_{n-1}$, then no subset $J \subset\{1, \ldots, n\}$ satisfies the four conditions of Definition 1.4.3 simultaneously. Thus in this case $\beta_{k}\left(\ell^{+}, \ell^{-}\right)=0$ for all $k$.

We now assume that $\ell^{-}$and $\ell^{+}$are length vectors as in the third claim of the proposition. Since $\ell, \ell^{-}$and $\ell^{+}$lie in the same chamber,

$$
\alpha_{k}\left(\ell^{-}\right)=\alpha_{k}\left(\ell^{+}\right)=\alpha_{k}(\ell) \text { and } \beta_{k}\left(\ell^{-}, \ell^{+}\right)=\beta_{k}(\ell, \ell)
$$

for all $k$. It follows from Definition 1.4.1 that if $l_{n-1} \leq l_{n}$, then the numbers $\alpha_{k}(\ell)$ and $a_{k}(\ell)$ coincide for all $k$. On the other hand, by the second part of the proposition, in this case all the numbers $\beta_{k}(\ell, \ell)$ vanish. This proves the third claim of the proposition in the case $l_{n-1} \leq l_{n}$.

Assume now the inequality $l_{n-1}>l_{n}$. We write the set $\mathcal{S}_{n}(\ell)$ as a disjoint union

$$
\mathcal{S}_{n}(\ell)=A \cup B \cup C
$$

of subsets of the following form:

- $A$ is the family of all subsets $J \subset\{1, \ldots, n\}$ so that $n-1, n \in J$ and $J$ is short with respect to $\ell$.
- $B$ is the family of all subsets $J \subset\{1, \ldots, n\}$ so that $n \in J, n-1 \notin J$ and the sets $J$ and $J-\{n\} \cup\{n-1\}$ are both short with respect to $\ell$.
- $C$ is the family of all subsets $J \subset\{1, \ldots, n\}$ so that $n-1 \notin J, J$ is short with respect to $\ell$ and the set $J-\{n\} \cup\{n-1\}$ is long with respect to $\ell$.

Since $l_{n-1}>l_{n}$, for every subset $J \subset\{1, \ldots, n\}$ which is short with respect to $\ell$ and satisfies $n-1 \in J$ and $n \notin J$, the set $J-\{n-1\} \cup\{n\}$ is again short with respect to $\ell$. Thus the set $B$ is in bijection with the set of all $J \subset\{1, \ldots, n\}$ so that $n-1 \in J, n \notin J$ and $J$ is short with respect to $\ell$. It follows that the number of elements $J \in A \cup B$ with $|J|=k+1$ is $a_{k}(\ell)$. On the other hand, one concludes from Definitions 1.4 .1 and 1.4 .3 that the number of elements $J \in S_{n}(\ell)$ (respectively $J \in C$ ) with $|J|=k+1$ is $\alpha_{k}(\ell)$ (respectively $\beta_{k}(\ell, \ell)$ ). It follows that $\alpha_{k}(\ell)=a_{k}(\ell)+\beta_{k}(\ell, \ell)$.

### 1.5 Basic Properties of the Spaces

In this section we relate basic properties of the spaces $E_{d}(\ell)$ and $E_{d}(A)$ such as non-emptiness and smoothness to combinatorial properties of length vectors.

Proposition 1.5.1. 1. Let $\ell$ be a length vector and let $m \in\{1, \ldots, n\}$ be the index of any maximal entry of $\ell$. The space $E_{d}(\ell)$ is non-empty if and only if the one-element set $\{m\}$ is short or median with respect to $\ell$.
2. Consider a polygonal telescopic linkage with metric data $A$ given by length vectors $\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{-}\right)$and $\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{+}\right)$. Let $k \in\{1, \ldots, n-1\}$ be the index of any maximal entry of $\left(l_{1}, \ldots, l_{n-1}\right)$. The space $E_{d}(A)$ is nonempty if and only if the one-element set $\{n\}$ is short or median with respect to $\ell^{-}$and the one-element set $\{k\}$ is short or median with respect to $\ell^{+}$.

Proof. It follows from the definition of the space $E_{d}(\ell)$ and the triangle inequality that a necessary condition for $E_{d}(\ell)$ to be non-empty is that the one-element set $\{m\}$ be short or median with respect to $\ell$. By the first part of Proposition 1.2.2, this condition is also sufficient if $n=3$. Let us show that the condition is sufficient for every $n \geq 3$.

Assume that the set $\{m\}$ is short or median with respect to $\ell$. Let $J \subset\{1, \ldots, n\}$ be a maximal subset satisfying the conditions

Then $J \neq \emptyset$ since otherwise every one-element set $\{k\} \subset\{1, \ldots, n\}$ would be long or median with respect to $\ell$, contradicting the assumption $n \geq 3$. Moreover, $\bar{J} \neq\{m\}$ since the complement of a short subset is long. It follows that the set $I=\bar{J}-\{m\}$ is non-empty.

We note that $I$ is either short or median with respect to $\ell$. Indeed, if $I$ were long, then using the fact that $m$ is the index of a maximal entry of $\ell$, one would obtain that for every $i \in I$ the set $J \cup\{i\}$ is short with respect to $\ell$, contradicting the choice of $J$. We have found a partition

$$
\{1, \ldots, n\}-\{m\}=I \cup J
$$

so that $I, J \neq \emptyset$ and the sets $I, J$ are both short or median with respect to $\ell$.

The length vector $L$ with entries

$$
L_{1}=\sum_{j \in J} l_{j}, L_{2}=\sum_{j \in I} l_{j} \text { and } L_{3}=l_{m}
$$

satisfies the condition of the first part of the proposition with $n=3$, as every oneelement subset $\{j\} \subset\{1,2,3\}$ is either short or median with respect to $L$. We conclude that $E_{d}(L) \neq \emptyset$. On the other hand, every element of the space $E_{d}(L)$ may be viewed as a polygon in $E_{d}(\ell)$ so that all the edges with indices in $I$ are collinear and so are all the edges with indices in $J$. Thus $E_{d}(\ell) \neq \emptyset$.

We now demonstrate the second assertion of the proposition. If $E_{d}(A) \neq \emptyset$, then there exists a length vector $\ell=\left(l_{1}, \ldots, l_{n}\right) \in A$ with $E_{d}(\ell) \neq \emptyset$. Using the first part of the proposition, it follows that each of the sets $\{k\}$ and $\{n\}$ is either short or median with respect to $\ell$. Since $l_{n}^{-} \leq l_{n} \leq l_{n}^{+}$, one concludes that the set $\{n\}$ is short or median with respect to $\ell^{-}$and the set $\{k\}$ is short or median with respect to $\ell^{+}$.

We now show that if $E_{d}(A)=\emptyset$, then one of the two sets $\{k\},\{n\}$ must be long with respect to both $\ell^{-}$and $\ell^{+}$. This will complete the proof.

If the space $E_{d}(A)$ is empty, then so is the space $E_{d}\left(\ell^{-}\right)$. Using the first part of the proposition, it follows that in this case one of the sets $\{k\},\{n\}$ is long with respect to $\ell^{-}$. If the set $\{n\}$ is long with respect to $\ell^{-}$, then it is also long with respect to $\ell^{+}$. If $\{k\}$ were long with respect to $\ell^{-}$but short or median with respect to $\ell^{+}$, there would exist $\ell \in A$ so that $\{k\}$ is median with respect to $\ell$. But then by the first part of the proposition $E_{d}(\ell) \neq \emptyset$ contradicting the assumption that the space $E_{d}(A)$ is empty.

It follows from Definition 1.1.1 that the subset $E_{d}(\ell) \subset W$ is invariant under the diagonal action of the orthogonal groups $S O(d)$ and $O(d)$ on $W=\left(S^{d-1}\right)^{n}$.

Proposition 1.5.2. 1. The $S O(2)$-action on the space $E_{2}(\ell)$ is free. If $M_{\ell}$ denotes the quotient space

$$
M_{\ell}=E_{2}(\ell) / S O(2)
$$

then there is a homeomorphism

$$
E_{2}(\ell) \simeq S^{1} \times M_{\ell}
$$

2. The action of $S O(3)$ on $E_{3}(\ell)$ is free if and only if the length vector $\ell$ is generic.
3. If $d>3$ and $E_{d}(\ell) \neq \emptyset$, then the $S O(d)$-action on $E_{d}(\ell)$ is not free.

Proof. For $d=2$, the group $S O(2)$ acts freely on $W=\left(S^{1}\right)^{n}$ and hence also on $E_{2}(\ell) \subset W$. The space $M_{\ell}$ can be identified with the subset of $E_{2}(\ell)$ consisting of those tuples $u=\left(u_{1}, \ldots, u_{n}\right) \in E_{2}(\ell) \subset W$, where $u_{1}=e$ is a given fixed element of $S^{1}$. A homeomorphism $\phi: S^{1} \times M_{\ell} \rightarrow E_{2}(\ell)$ is defined by $\phi(\theta, u)=\left(\theta e, \theta u_{2}, \ldots, \theta u_{n}\right)$ for $\theta \in S^{1}$ and $u=\left(e, u_{2}, \ldots, u_{n}\right) \in M_{\ell}$.

For $d=3$, the isotropy subgroup of an element $\left(u_{1}, \ldots, u_{n}\right) \in\left(S^{d-1}\right)^{n}=W$ is non-trivial if and only if $u_{j}= \pm u_{k}$ for all $j, k \in\{1, \ldots, n\}$. The subset $E_{d}(\ell) \subset W$ contains elements $\left(u_{1}, \ldots, u_{n}\right)$ of this form if and only if the length vector $\ell$ is nongeneric.

If $d>3$, then every planar configuration in $E_{d}(\ell)$ (that is a configuration where the edges of the polygon lie in a two-dimensional subspace $E \subset \mathbb{R}^{d}$ ) has a nontrivial isotropy subgroup, since such a configuration is fixed by every element of $S O(d)$ which fixes $E$. It follows from the proof of Proposition 1.5.1 that if the space $E_{d}(\ell)$ is non-empty, then it contains a planar configuration.

Proposition 1.5.3. 1. Let $\ell$ and $\ell^{\prime}$ be two length vectors, so that $\ell^{\prime}$ can be obtained from $\ell$ by a permutation of the entries. Then the spaces $E_{d}(\ell)$ and $E_{d}\left(\ell^{\prime}\right)$ may be naturally identified.
2. If the length vector $\ell$ is generic, then the space $E_{d}(\ell)$ is a closed oriented manifold of dimension

$$
\operatorname{dim} E_{d}(\ell)=(d-1)(n-1)-1
$$

3. If two generic length vectors $\ell$ and $\ell^{\prime}$ lie in the same chamber, then the spaces $E_{d}(\ell)$ and $E_{d}\left(\ell^{\prime}\right)$ are $O(d)$-equivariantly diffeomorphic.

To prove Proposition 1.5.3, consider $F:\left(\mathbb{R}^{d}\right)^{n-1} \rightarrow \mathbb{R}^{n}$,

$$
F\left(v_{1}, \ldots, v_{n-1}\right)=\left(\left|v_{1}\right|,\left|v_{2}-v_{1}\right|, \ldots,\left|v_{n-1}-v_{n-2}\right|,\left|v_{n-1}\right|\right) .
$$

The map $F$ is continuous and its restriction to the open subset $X \subset\left(\mathbb{R}^{d}\right)^{n-1}$ given by the inequalities

$$
v_{1} \neq 0, v_{n-1} \neq 0 \text { and } v_{j+1} \neq v_{j} \text { for } j=1, \ldots, n-2
$$

is smooth. Moreover, $F(X)=\mathbb{R}_{>0}^{n}$.
Lemma 1.5.4. Every generic length vector is a regular value of $F: X \rightarrow \mathbb{R}_{>0}^{n}$.

Proof. We will show that the critical points of $\left.F\right|_{X}$ are exactly those tuples

$$
v=\left(v_{1}, \ldots, v_{n-1}\right) \in X
$$

so that all the vectors $v_{j} \in \mathbb{R}^{d}, j=1, \ldots, n-1$ are collinear. Since for a length vector $\ell \in \mathbb{R}_{>0}^{n}$ the preimage $F^{-1}(\ell)$ contains points $v$ of this form if and only if $\ell$ is
non-generic, this will imply the claim.

Let $V=\left(V_{1}, \ldots, V_{n-1}\right) \in T_{v}\left(\mathbb{R}^{d}\right)^{n-1}$. Denote

$$
\begin{gathered}
u_{1}=\frac{1}{l_{1}} v_{1}, u_{n}=-\frac{1}{l_{n}} v_{n-1} \\
u_{j}=\frac{1}{l_{j}}\left(v_{j}-v_{j-1}\right), 2 \leq j \leq n-1
\end{gathered}
$$

and write $\langle\cdot, \cdot\rangle$ for the standard scalar product on $\mathbb{R}^{d}$. The derivative $D_{V} F$ of $F$ in direction $V$ is the vector in $\mathbb{R}^{n}$ with entries

$$
\begin{gathered}
\left(D_{V} F\right)_{1}=\left\langle V_{1}, u_{1}\right\rangle \\
\left(D_{V} F\right)_{j}=\left\langle V_{j}-V_{j-1}, u_{j}\right\rangle, j=2, \ldots, n-1
\end{gathered}
$$

and

$$
\left(D_{V} F\right)_{n}=-\left\langle V_{n-1}, u_{n}\right\rangle .
$$

Let $v$ be a critical point of $F$. Then there exists

$$
\epsilon=\left(\epsilon_{1}, \ldots, \epsilon_{n}\right) \in \mathbb{R}^{n}, \epsilon \neq 0
$$

so that the image of the derivative of $F$ at $v$ is contained in the hyperplane orthogonal to $\epsilon$. Thus in this case

$$
\sum_{j=1}^{n-1}\left\langle V_{j}, \epsilon_{j} u_{j}-\epsilon_{j+1} u_{j+1}\right\rangle=0
$$

for all $V_{1}, \ldots, V_{n-1}$. This implies that $u_{1}, \ldots, u_{n}$ satisfy

$$
\epsilon_{j} u_{j}=\epsilon_{j+1} u_{j+1}
$$

for $j=1, \ldots, n-1$. Thus the vectors $u_{1}, \ldots, u_{n}$, and hence also $v_{1}, \ldots, v_{n-1}$ are collinear.

Proof of Proposition 1.5.3. The first assertion follows from the fact that a permutation $\sigma$ of the indices $1, \ldots, n$ defines a diffeomorphism $W \rightarrow W$ which maps $E_{d}(\ell)$ onto $E_{d}(\sigma(\ell))$.

Identifying

$$
E_{d}(\ell) \simeq F^{-1}(\ell)
$$

the second claim follows from Lemma 1.5.4.

To prove the third assertion, let $\ell$ and $\ell^{\prime}$ be two generic length vectors which lie in the same chamber. Denote by $\left[\ell, \ell^{\prime}\right] \subset \mathbb{R}^{n}$ the closed interval connecting $\ell$ and $\ell^{\prime}$. Since every length vector $\ell^{\prime \prime} \in\left[\ell, \ell^{\prime}\right]$ is generic, $F^{-1}\left(\left[\ell, \ell^{\prime}\right]\right)$ is a smooth cobordism between $E_{d}(\ell)$ and $E_{d}\left(\ell^{\prime}\right)$. As

$$
F: F^{-1}\left(\left[\ell, \ell^{\prime}\right]\right) \rightarrow\left[\ell, \ell^{\prime}\right]
$$

is a smooth function without critical points, this cobordism is trivial and therefore there is a diffeomorphism $E_{d}(\ell) \simeq E_{d}\left(\ell^{\prime}\right)$.

Since $F$ is invariant under the diagonal action of the orthogonal group $O(d)$ on $\left(\mathbb{R}^{d}\right)^{n-1}$, so is the projection $\pi: F^{-1}\left(\left[\ell, \ell^{\prime}\right]\right) \rightarrow I$. Consider the flow of the gradient of $\pi$ with respect to the metric on $F^{-1}\left(\left[\ell, \ell^{\prime}\right]\right) \subset\left(\mathbb{R}^{d}\right)^{n-1}$ induced by the Euclidean metric. The flow defines a diffeomorphism $E_{d}(\ell) \rightarrow E_{d}\left(\ell^{\prime}\right)$ and since both $\pi$ and the metric are $O(d)$-invariant, this is an equivariant diffeomorphism.

We now state the analogue of Proposition 1.5 .3 for polygons with a telescopic edge.

We shall call the metric data $A$ of the telescopic linkage generic if both length vectors $\ell^{-}$and $\ell^{+}$are generic.

Proposition 1.5.5. Suppose that $A$ is generic.

1. The space $E_{d}(A)$ is a compact oriented manifold of dimension

$$
\operatorname{dim} E_{d}(A)=(d-1)(n-1) .
$$

The boundary of $E_{d}(A)$ is given by the disjoint union of the spaces $E_{d}\left(\ell^{-}\right)$and $E_{d}\left(\ell^{+}\right)$.
2. Let $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ be a permutation which fixes the index $n$. Let $\sigma(A)$ be the metric data of the polygonal telescopic linkage described by the length vectors $\sigma\left(\ell^{-}\right)$and $\sigma\left(\ell^{+}\right)$. Then the spaces $E_{d}(A)$ and $E_{d}(\sigma(A))$ are $O(d)$-equivariantly diffeomorphic.

Proposition 1.5.6. Let $\ell=\left(l_{1}, \ldots, l_{n}\right)$ be generic, let $0<\varepsilon<\min \left(l_{n},[\ell]\right)$ and let

$$
\begin{aligned}
\ell^{-} & =\left(l_{1}, \ldots, l_{n-1}, l_{n}-\varepsilon\right), \\
\ell^{+} & =\left(l_{1}, \ldots, l_{n-1}, l_{n}+\varepsilon\right)
\end{aligned}
$$

be length vectors as in Proposition 1.3.5. Let $A$ be the metric data of the polygonal telescopic linkage corresponding to $\ell^{-}$and $\ell^{+}$. Then there is an $O(d)$-equivariant diffeomorophism

$$
E_{d}(A) \simeq E_{d}(\ell) \times[-\varepsilon, \varepsilon] .
$$

The proofs of Propositions 1.5 .5 and 1.5 .6 are given in the next section.

### 1.6 The Robot Arm Distance Map

In this section we introduce the robot arm distance map and study its properties. We determine the space $E_{d}(\ell)$ explicitly in some important special cases.

The proofs of many subsequent results concerning the topology of the spaces $E_{d}(\ell)$ rely on the special properties of a certain function on $W=\left(S^{d-1}\right)^{n}$ that we now introduce.

Lemma 1.6.1. Let $\ell$ be a length vector. Consider the function

$$
f_{\ell}: W \rightarrow \mathbb{R}, f_{\ell}\left(u_{1}, \ldots, u_{n}\right)=-\left|\sum_{j=1}^{n} l_{j} u_{j}\right|^{2}
$$

1. The critical points of $f_{\ell}$ are given by the union of $f_{\ell}^{-1}(0)=E_{d}(\ell)$ and all the submanifolds

$$
P_{J}=\left\{\left(u_{1}, \ldots, u_{n}\right): u_{j}=u_{k}=-u_{m} \text { for } j, k \in J, m \notin J\right\},
$$

so that the subset $J \subset\{1, \ldots, n\}$ is long with respect to $\ell$.
2. For every subset $J \subset\{1, \ldots, n\}$ which is long with respect to $\ell$, the critical submanifold $P_{J}$ is nondegenerate in the sense of Bott. Its Morse-Bott index is given by

$$
i n d_{f_{\ell}}\left(P_{J}\right)=(d-1)(n-|J|) .
$$

Remark 1.6.2. The function $f_{\ell}$ is called the robot arm distance map. Recall from Section 1.2 that $W=\left(S^{d-1}\right)^{n}$ may be viewed as the configuration space of a robot arm in Euclidean space of dimension $d$. If the segments of the robot arm have length $l_{1}, \ldots, l_{n}$, then the function $f_{\ell}$ measures the distance between the grip and the endpoint of the arm. The space $E_{d}(\ell)$ is the subset of $W$ consisting of those configurations of the robot arm, so that the endpoint of the arm lies at the grip.

The first part of Lemma 1.6 .1 states that the critical points of $f_{\ell}$ consist of the zero level set $f_{\ell}^{-1}(0)=E_{d}(\ell)$ as well as of all those configurations of the robot arm, so that all the segments are collinear.

The second part of Lemma 1.6.1 implies that the restriction of $f_{\ell}$ to the complement $W-E_{d}(\ell)$ is a Morse-Bott function with the property that every critical submanifold is diffeomorphic to the sphere $S^{d-1}$ and has a Morse-Bott index which is a multiple of $d-1$. In the next chapter, we develop an analogue of the classical Morse lacunary principle that applies to Morse-Bott functions of this type.

Proof. For $u \in S^{d-1}$, identify

$$
T_{u} S^{d-1} \simeq\left\{v \in \mathbb{R}^{d}:\langle u, v\rangle=0\right\}
$$

Let $\left(v_{1}, \ldots, v_{n}\right) \in T_{\left(u_{1}, \ldots, u_{n}\right)} W$. For $j=1, \ldots, n$, the derivative of $f_{\ell}$ in direction $v_{j}$ is

$$
D_{v_{j}} f_{\ell}=-2\left\langle l_{j} v_{j}, \sum_{i=1, \ldots, n} l_{i} u_{i}\right\rangle .
$$

At a critical point $\left(u_{1}, \ldots, u_{n}\right)$ of $f_{\ell}$, the equation $D_{v_{j}} f_{\ell}=0$ holds for $j=1, \ldots, n$. It follows that if $f_{\ell}\left(u_{1}, \ldots, u_{n}\right) \neq 0$, then for each $j=1, \ldots, n$ the vector $u_{j}$ is collinear to the sum $\sum_{i=1, \ldots, n-1} l_{i} u_{i}$. Thus the critical points of $f_{\ell}$ are those tuples $\left(u_{1}, \ldots, u_{n}\right)$, where either $f_{\ell}\left(u_{1}, \ldots, u_{n}\right)=0$ or $u_{j}= \pm u_{k}$ for all $j, k$. This proves the first assertion.

To establish the second assertion, fix an element $p \in S^{d-1}$ and consider for every subset $J \subset\{1, \ldots, n\}$ which is long with respect to $\ell$ the point $p_{J} \in P_{J}$ given
by

$$
u_{j}= \begin{cases}p & \text { if } j \in J \\ -p & \text { if } j \notin J\end{cases}
$$

We want to compute explicitly the Hessian of $f_{\ell}$ at the critical point $p_{J}$. By symmetry, it suffices to consider the case $p=e_{1}=(1,0, \ldots, 0)$. Parametrize $S^{d-1}$ in a neighbourhood of $e_{1}$ by the map

$$
\begin{gathered}
\mathbb{R}^{d-1} \rightarrow S^{d-1} \subset \mathbb{R}^{d}, \\
\left(r_{2}, \ldots, r_{d}\right) \mapsto \frac{1}{\left(1+\sum_{2 \leq j \leq d} r_{j}^{2}\right)^{1 / 2}}\left(e_{1}+\sum_{2 \leq j \leq d} r_{j} e_{j}\right)
\end{gathered}
$$

and in a neighbourhood of $-e_{1}$ by

$$
\begin{gathered}
\mathbb{R}^{d-1} \rightarrow S^{d-1} \subset \mathbb{R}^{d}, \\
\left(r_{2}, \ldots, r_{d}\right) \mapsto-\frac{1}{\left(1+\sum_{2 \leq j \leq d} r_{j}^{2}\right)^{1 / 2}}\left(e_{1}+\sum_{2 \leq j \leq d} r_{j} e_{j}\right) .
\end{gathered}
$$

We can express the second derivatives of $f_{\ell}$ at the point $p_{J}$ as follows:

$$
\frac{\partial^{2}}{\partial r_{k_{1}}^{\left(j_{1}\right)} \partial r_{k_{2}}^{\left(j_{2}\right)}} f_{\ell}= \begin{cases}-2 l_{j}^{2}+2 \epsilon_{J}(j) l_{j} \ell_{J} & \text { if }\left(k_{1}, j_{1}\right)=\left(k_{2}, j_{2}\right)=(k, j) \\ -2 l_{j_{1}} l_{j_{2}} & \text { if } k_{1}=k_{2}, j_{1} \neq j_{2}, \\ 0 & \text { if } k_{1} \neq k_{2}\end{cases}
$$

Here $k_{1}, k_{2} \in\{2, \ldots, d\}, j_{1}, j_{2} \in\{1, \ldots, n\}$ and

$$
\epsilon_{J}(j)= \begin{cases}+1 & \text { if } j \in J \\ -1 & \text { if } j \notin J .\end{cases}
$$

We also recall the notation

$$
\ell_{J}=\sum_{j \in J} l_{j}-\sum_{j \notin J} l_{j} .
$$

It follows that the Hessian of $f_{\ell}$ at $p_{J}$ is congruent to a $(d-1) n \times(d-1) n$-matrix $A$ of the following form. Let $D \in \mathbb{R}^{n \times n}$ be the diagonal matrix whose $j$ th diagonal entry for $j=1, \ldots, n$ is

$$
(D)_{j j}=\frac{\epsilon_{J}(j)}{l_{j}} \ell_{J}
$$

and $E \in \mathbb{R}^{n \times n}$ be the matrix with all entries equal to 1 . Then $A$ is obtained from the difference $D-E$ by interchanging every entry $\lambda$ with the matrix $\lambda I_{d-1}$ where $I_{d-1} \in \mathbb{R}^{(d-1) \times(d-1)}$ is the identity matrix. Thus the Hessian of $f_{\ell}$ has the same eigenvalues as the matrix $D-E$ and the multiplicity of every eigenvalue is multiplied by $(d-1)$. Using the computation in [7], Lemma 1.4, the index of the Hessian is $(n-|J|)(d-1)$ and the multiplicity of the zero eigenvalue is $d-1$. Since $d-1$ is also the dimension of the critical submanifold $P_{J}$, it follows that it is nondegenerate in the sense of Bott.

We can now give the proofs of Propositions 1.5.5 and 1.5.6.

Proof of Propositions 1.5.5 and 1.5.6. Let $A$ be the metric data of a telescopic linkage defined by $\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{-}\right)$and $\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{+}\right)$. Denoting by $\ell^{\prime}$ the length vector $\ell^{\prime}=\left(l_{1}, \ldots, l_{n-1}\right)$, the space $E_{d}(A)$ may be identified with the preimage $f_{\ell^{\prime}}^{-1}([a, b])$, where

$$
a=-\left(l_{n}^{+}\right)^{2} \text { and } b=-\left(l_{n}^{-}\right)^{2} .
$$

Moreover, $f_{\ell^{\prime}}^{-1}(a)=E_{d}\left(\ell^{+}\right)$and $f_{\ell^{\prime}}^{-1}(b)=E_{d}\left(\ell^{-}\right)$.

By Proposition 1.6.1, the critical values of $f_{\ell^{\prime}}$ consist of 0 and all the numbers of the form $-\left|\sum_{j=1}^{n-1} \epsilon_{j} l_{j}\right|^{2}$, where $\epsilon_{j}= \pm 1$. Thus $a$ and $b$ are regular values of $f_{\ell^{\prime}}$ if and only if the length vectors $\ell^{-}$and $\ell^{+}$are both generic. In this case $E_{d}(A)=f_{\ell^{\prime}}^{-1}([a, b])$ is a manifold whose boundary is given by the disjoint union of $f_{\ell^{\prime}}^{-1}(a)=E_{d}\left(\ell^{+}\right)$and $f_{\ell^{\prime}}^{-1}(b)=E_{d}\left(\ell^{-}\right)$. This proves the first claim of Proposition 1.5.5. The proof of the second claim is analogous to that of the first part of Proposition 1.5.3.

If $\ell$ is generic and $\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}-\varepsilon\right), \ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}+\varepsilon\right), 0<\varepsilon<$ $\min \left(l_{n},[\ell]\right)$ are length vectors as in Proposition 1.3.5, then every element of $A$ is a generic length vector. Thus in this case the function $f_{\ell^{\prime}}$ has no critical values in the interval $[a, b]$ and hence there are diffeomorphisms

$$
E_{d}(A) \simeq f_{\ell^{\prime}}^{-1}([a, b]) \simeq f_{\ell^{\prime}}^{-1}\left(-l_{n}^{2}\right) \times[a, b] \simeq E_{d}(\ell) \times[a, b] .
$$

Since the function $f_{\ell^{\prime}}$ is $O(d)$-invariant, the same argument as used in the proof of the first part of Proposition 1.5 .3 shows that the diffeomorphism $E_{d}(A) \simeq E_{d}(\ell) \times[a, b]$ may be chosen to be $O(d)$-equivariant.

Let $\ell$ be a generic length vector. We say that $J \subset\{1, \ldots, n\}$ is a maximal short subset if $J$ is short with respect to $\ell$ and if for every proper inclusion $J \subsetneq K \subset$ $\{1, \ldots, n\}$ the subset $K$ is long with respect to $\ell$. We say that there is a massive $e d g e$ if there exists a maximal short one-element subset $\{m\} \subset\{1, \ldots, n\}$. Using the numerical quantities $a_{k}(\ell)$ introduced in Section 1.4 , this condition can equivalently be expressed by the two equations

$$
a_{0}(\ell)=1, a_{1}(\ell)=0
$$

Proposition 1.6.3 (The case of a massive edge). Suppose that a generic length vector $\ell$ admits a maximal short one-element subset $\{m\} \subset\{1, \ldots, n\}$. If $n=3$, then there is a diffeomorphism

$$
E_{d}(\ell) \simeq T^{1} S^{d-1}
$$

If $n>3$, then the space $E_{d}(\ell)$ is diffeomorphic to a product of two spheres:

$$
E_{d}(\ell) \simeq S^{(d-1)(n-2)-1} \times S^{d-1}
$$

Remark 1.6.4. The assumption of Proposition 1.6 .3 determines the chamber of the length vector $\ell$ uniquely up to permutation of the entries of $\ell$. Indeed, in this case a subset $J \subset\{1, \ldots, n\}$ is short with respect to $\ell$ if either $J=\{m\}$ or $m \notin J$ and $|J|<n-1$, and long otherwise.

Proof of Proposition 1.6.3. Using the first part of Proposition 1.5.3, we can assume without loss of generality that $m=n$ is the index of the last entry of $\ell$. Denote by $\ell^{\prime}=\left(l_{1}, \ldots, l_{n-1}\right)$ the length vector obtained from $\ell$ by erasing the last entry and consider the function $f_{\ell^{\prime}}:\left(S^{d-1}\right)^{n-1} \rightarrow \mathbb{R}$. We identify

$$
E_{d}(\ell)=f_{\ell^{\prime}}^{-1}\left(-l_{n}^{2}\right)
$$

The minimal value if $f_{\ell^{\prime}}$ is $-L^{2}$, where $L=l_{1}+\cdots+l_{n-1}$. The preimage $f_{\ell^{\prime}}^{-1}\left(-L^{2}\right)$ is the diagonal $\Delta \subset\left(S^{d-1}\right)^{n-1}$. By Lemma 1.6.1, $f_{\ell^{\prime}}^{-1}\left(-L^{2}\right)$ is a critical submanifold
which is nondegenerate in the sense of Bott. Moreover, critical values of $f_{\ell^{\prime}}$ which lie in the interval $\left[-L^{2},-l_{n}^{2}\right]$ correspond to subsets of $\{1, \ldots, n\}$ which are long with respect to $\ell$ and do not containing the index $n$. Since under the assumptions of the proposition the only subset of this form is $\{1, \ldots, n-1\}$, we find that $-L^{2}$ is the only critical value contained in this interval. It follows that $E_{d}(\ell)$ is diffeomorphic to the space of unit vectors in the normal bundle $\nu$ to the diagonal $\Delta \subset\left(S^{d-1}\right)^{n-1}$. To identify this latter space, we note that the bundle $\nu$ is isomorphic to the Whitney sum of $n-2$ copies of the tangent bundle of the sphere $S^{d-1}$ :

$$
\nu \simeq \underset{n-2}{\oplus} T S^{d-1}
$$

It follows that if $n=3$, then there is a diffeomorphism

$$
E_{d}(\ell) \simeq T^{1} S^{d-1}
$$

Assume now that $n>3$. We claim that in this case the vector bundle $\nu$ is trivial. To prove this, the criterion of Theorem 1.5 in Chapter 9 of [24] will be used. Let $\tau$ denote the tangent bundle of $S^{d-1}$ and $\theta^{k}$ the trivial bundle of rank $k$ over $S^{d-1}$. Since the Whitney sum $\tau \oplus \theta^{1}$ is trivial, so is

$$
\nu \oplus \theta^{n-2}=\oplus_{n-2}(\tau \oplus \theta) .
$$

Since for $n>3$ the rank $(d-1)(n-2)$ of the bundle $\nu$ is greater than the dimension $d-1$ of its base, the aforementioned theorem in [24] shows that triviality of $\nu \oplus \theta^{n-2}$ implies the triviality of $\nu$. It follows that in the case $n>3$ there is a diffeomorphism

$$
E_{d}(\ell) \simeq S^{(d-1)(n-2)-1} \times S^{d-1}
$$

This completes the proof.
Let us now study how the space $E_{d}(\ell)$ changes when a small edge is inserted into the polygon.

Proposition 1.6.5 (Inserting a small edge). Let $\ell$ be a generic length vector and let $0<\varepsilon<[\ell]$ (see Section 1.3 for the definition of the quantity $[\ell]$ ). Denote by $(\varepsilon, \ell)$ the length vector obtained from $\ell$ by inserting $\varepsilon$ as the first entry. Then there is a diffeomorphism

$$
E_{d}(\varepsilon, \ell) \simeq S^{d-1} \times E_{d}(\ell)
$$

Proof. Consider the map

$$
\begin{gathered}
\widehat{F}:\left(\mathbb{R}^{d}\right)^{n} \rightarrow \mathbb{R}^{d} \times \mathbb{R}^{n} \\
\left(v_{1}, \ldots, v_{n}\right) \mapsto\left(v_{1},\left|v_{2}-v_{1}\right|, \ldots,\left|v_{n}-v_{n-1}\right|,\left|v_{n}\right|\right) .
\end{gathered}
$$

We note that $\widehat{F}$ is smooth on the open subset $Y \subset\left(\mathbb{R}^{d}\right)^{n}$ defined by the inequalities

$$
v_{n} \neq 0 \text { and } v_{j+1} \neq v_{j} \text { for } j=1, \ldots, n-1
$$

It follows from the proof of Lemma 1.5.4 that every critical point of $\left.\widehat{F}\right|_{Y}$ is a tuple $\left(v_{1}, \ldots, v_{n}\right)$ so that all the vectors $v_{j}, j=1, \ldots, n$ are collinear. Thus every vector of the form $\left(v_{1}, \ell\right) \in \mathbb{R}^{d} \times \mathbb{R}^{n}, 0<\left|v_{1}\right|<[\ell]$, is a regular value of $\left.\widehat{F}\right|_{Y}$. Moreover, since $\ell$ is generic, the vector $(0, \ell)$ is a regular value of $\left.\widehat{F}\right|_{Y}$.

Denote by $B_{\varepsilon}(0) \subset \mathbb{R}^{d}$ the closed ball of radius $\varepsilon$ centred at the origin. We identify

$$
E_{d}(\varepsilon, \ell)=\widehat{F}^{-1}\left(\partial B_{\varepsilon}(0) \times\{\ell\}\right)
$$

Since the map $\widehat{F}$ has no critical values in $B_{\varepsilon}(0) \times\{\ell\}$, there are diffeomorphisms

$$
E_{d}(\varepsilon, \ell) \simeq \widehat{F}^{-1}\left(\partial B_{\varepsilon}(0) \times\{\ell\}\right) \simeq S^{d-1} \times \widehat{F}^{-1}(0, \ell) \simeq S^{d-1} \times E_{d}(\ell)
$$

Let $\ell$ be a length vector. We say that there is a massive triangle if there are pairwise distinct indices $i, j, k \in\{1, \ldots, n\}$ so that the two-element sets $\{i, j\},\{i, k\}$ and $\{j, k\}$ are long with respect to $\ell$. In this case one of the indices $i, j, k$ must be the index of a maximal entry of $\ell$. Moreover, a subset $J \subset\{1, \ldots, n\}$ is long with respect to $\ell$ if $J$ contains at least two of the indices $i, j, k$, and short otherwise. Thus existence of a massive triangle implies that the length vector $\ell$ is generic and determines its chamber uniquely up to permutation of the entries of $\ell$.

Existence of indices $i, j, k$ as above is equivalent to the number $a_{n-3}(\ell)$ being nonzero. Indeed, it follows from Definition 1.4.1 that $a_{n-3}(\ell)$ is the number of long twoelement subsets of $\{1, \ldots, n\}$ not containing the index of a maximal entry. Thus $a_{n-3}(\ell) \neq 0$ if there is a massive triangle. Conversely, if $a_{n-3}(\ell) \neq 0$, then there
exists a long subset $J=\left\{j_{1}, j_{2}\right\} \subset\{1, \ldots, n\}$ not containing the index $m$ of the maximal entry, but then the three indices $j_{1}, j_{2}, m$ satisfy the above condition.

Proposition 1.6.6 (The case of a massive triangle). If $a_{n-3}(\ell) \neq 0$, then $\ell$ is generic and there is a diffeomorphism

$$
E_{d}(\ell) \simeq\left(S^{d-1}\right)^{n-3} \times T^{1} S^{d-1}
$$

Remark 1.6.7. The number $a_{n-3}(\ell)$ is either zero or one. Indeed, suppose that there existed two distinct long two-element sets $J=\left\{j_{1}, j_{2}\right\}$ and $K=\left\{k_{1}, k_{2}\right\}$ not containing the index $m$ of a maximal entry of $\ell$. Since the complement of a long subset is short, the intersection of $J$ and $K$ must be non-empty and we can assume that $j_{1}=k_{1}=j$. Since $J \neq K$, the indices $j_{2}$ and $k_{2}$ must be distinct. As $l_{n} \geq l_{j}$, we find that the two disjoint sets $\left\{j, j_{2}\right\}$ and $\left\{k_{2}, m\right\}$ are both long. This is a contradiction.

Proof of Proposition 1.6.6. Using the first part of Proposition 1.5.3, we can assume without loss of generality that the length vector $\ell$ is ordered. If $n=3$, then the diffeomorophism $E_{d}(\ell) \simeq T^{1} S^{d-1}$ follows from Proposition 1.6.3. Assume now that $n>3$.

Since $\ell$ is generic, by slightly changing one of the entries of $\ell$ if necessary, we may assume that the length vector $\ell^{\prime}=\left(l_{2}, \ldots, l_{n}\right)$ obtained by erasing the first entry of $\ell$ is generic. Let $0<\varepsilon<\left[\ell^{\prime}\right]$. We claim that the length vectors $\ell$ and $\left(\varepsilon, \ell^{\prime}\right)$ lie in the same chamber. Indeed, a subset $J \subset\{1, \ldots, n\}$ is long with respect to $\ell$ if and only if $J$ contains at least two of the three indices $n-2, n-1, n$ and this last condition is equivalent to $J$ being long with respect to $(\varepsilon, \ell)$. Using Propositions 1.5.3 and 1.6.5, it follows that

$$
E_{d}(\ell) \simeq S^{d-1} \times E_{d}\left(\ell^{\prime}\right)
$$

We note that the set $\{n-3, n-2\}$ is long with respect to $\ell^{\prime}$. Thus, arguing inductively, one finds $E_{d}(\ell) \simeq\left(S^{d-1}\right)^{n-3} \times T^{1} S^{d-1}$. This completes the proof.

We can now conclude Proposition 1.2 .3 as a corollary of Propositions 1.6 .3 and 1.6.6. Indeed, in the case of the first part of Proposition 1.2 .3 we have $a_{1}(\ell) \neq 0$ and the
homeomorphism $E_{d}(\ell) \simeq S^{d-1} \times T^{1} S^{d-1}$ follows from Proposition 1.6.6. In the situation of the second part of Proposition 1.2.3, the assumptions of Proposition 1.6.3 are satisfied and thus $E_{d}(\ell) \simeq S^{2(d-1)-1} \times S^{d-1}$.

We finish this chapter by using the robot arm distance map to study connectedness of the spaces $E_{d}(\ell)$.

Proposition 1.6.8. Assume that for some $k \geq 1$ the length vector $\ell$ does not admit long subsets $J \subset\{1, \ldots, n\}$ with $|J|=k$. Then the homomorphism

$$
\pi_{p}\left(E_{d}(\ell)\right) \rightarrow \pi_{p}\left(\left(S^{d-1}\right)^{n}\right)
$$

induced by inclusion is an isomorphism for $0 \leq p<(d-1) k-1$ and an epimorphism for $p=(d-1) k-1$.

Proof. Using Proposition 1.5.3, we can assume without loss of generality that the length vector $\ell$ is ordered. Consider the robot arm distance map $f_{\ell}:\left(S^{d-1}\right)^{n} \rightarrow \mathbb{R}$ defined in Proposition 1.6.1. Recall that the space $E_{d}(\ell)$ is the zero level set $f_{\ell}^{-1}(0)$.

Denote $t_{0}=0$ and let $t_{1}<t_{0}$ be a regular value of $f_{\ell}$ so that the interval $\left(t_{1}, t_{0}\right)$ contains no critical values. Moreover, let $t_{1}>t_{2}>\cdots>t_{s}$ be regular values of $f_{\ell}$ so that for each $i>0$ the interval $\left(t_{i+1}, t_{i}\right)$ contains a single critical value of $f_{\ell}$ and so that the image of $f_{\ell}$ is contained in the interval $\left[t_{0}, t_{s}\right)$. Consider the preimage $W_{i}=f_{\ell}^{-1}\left[t_{i}, t_{0}\right]$ for $i>0$. Since $t_{0}=0$ is the maximum of $f_{\ell}$ and since every $t_{i}$ with $i>0$ is a regular value of $f_{\ell}$, it follows that each subset $W_{i} \subset W$ is a manifold with boundary. The gradient flow of $f_{\ell}$ defines a deformation retraction of $W_{1}$ onto $E_{d}(\ell)=f_{\ell}^{-1}(0)$. The choice of $t_{s}$ implies that $W_{s}=\left(S^{d-1}\right)^{n}$.

By Lemma 1.6.1, the critical points of $f_{\ell}$ contained in $W_{i+1}-W_{i}$ lie on the submanifolds $P_{J} \subset\left(S^{d-1}\right)^{n}$, where $J \subset\{1, \ldots, n\}$ is long with respect to $\ell$ and $f_{\ell}\left(P_{J}\right) \in\left(t_{i+1}, t_{i}\right)$. Every critical submanifold $P_{J}$ is nondegenerate in the sense of Bott, homeomorphic to the sphere $S^{d-1}$ and has the Morse-Bott index

$$
\operatorname{ind}_{f_{\ell}}\left(P_{J}\right)=(d-1)(n-|J|) .
$$

Denote by $E_{J}^{-}$the unstable bundle of $P_{J}$ with respect to a gradient flow of $f_{\ell}$ and let $D_{J}^{-} \subset E_{J}^{-}$be the corresponding closed disk bundle. Thus the fibre of $D_{J}^{-}$is a disk of dimension $(d-1)(|J|-1)$.

Applying Theorem 2.43 from [34], one concludes that the inclusion into $W_{i+1}$ of the space

$$
\begin{equation*}
W_{i} \bigcup_{f_{\ell}\left(P_{J}\right) \in\left(t_{i+1}, t_{i}\right)}\left(\cup_{\partial D_{J}^{-}} D_{J}^{-}\right) \tag{1.2}
\end{equation*}
$$

obtained by attaching to $W_{i}$ the unstable disk bundles of all the critical submanifolds $P_{J}$ with $f_{\ell}\left(P_{J}\right) \in\left(t_{i+1}, t_{i}\right)$ is a homotopy equivalence. Using the cell decomposition of $P_{J} \simeq S^{d-1}$ into one zero-cell and one cell of dimension $(d-1)$, it follows that $W_{i+1}$ is homotopy equivalent to a space obtained from $W_{i}$ by attaching for every subset $J \subset\{1, \ldots, n-1\}$ with $f_{\ell}\left(P_{J}\right) \in\left(t_{i+1}, t_{i}\right)$ a cell of dimension $(d-1)(|J|-1)$ and then attaching to the resulting space a cell of dimension $(d-1)|J|$.

The above arguments show that if every subset $J \subset\{1, \ldots, n\}$ which is long with respect to $\ell$ has cardinality $|J|>k$, then each manifold $W_{i+1}$ is homotopy equivalent to a space obtained from $W_{i}$ by attaching cells of dimension at least $(d-1) k$. Thus in this case the homomorphism $\pi_{p}\left(W_{i}\right) \rightarrow \pi_{p}\left(W_{i+1}\right)$ induced by inclusion is an isomorphism for $p<(d-1) k-1$ and an epimorphism for $p=(d-1) k-1$ (see e.g. Corollary 4.12 in [19]). Arguing inductively, one concludes that the inclusion homomorphism $\pi_{p}\left(W_{1}\right) \rightarrow \pi_{p}\left(W_{s}\right)$ is an isomorphism for $p<(d-1) k-1$ and an epimorphism for $p=(d-1) k-1$. Since $W_{s}=\left(S^{d-1}\right)^{n}$ and since $E_{d}(\ell) \subset W_{1}$ is a deformation retract, this completes the proof.

It follows from Proposition 1.5 .1 that if the space $E_{d}(\ell)$ is non-empty, then every subset $J \subset\{1, \ldots, n\}$ which is long with respect to $\ell$ has at least two elements. Together with Proposition 1.6.8, we conclude:

Corollary 1.6.9. If $d>2$, then the space $E_{d}(\ell)$ is $(d-3)$-connected. In particular, in this case the space $E_{d}(\ell)$ is connected.

The second part of Proposition 1.2 .2 shows that the space $E_{d}(\ell)$ is not $(d-2)$ connected in general. However, one can show:

Proposition 1.6.10. Let $d \geq 2$. If $a_{n-3}(\ell)=0$ (compare with Proposition 1.6.6), then the space $E_{d}(\ell)$ is $(d-2)$-connected. In particular, in this case the space $E_{2}(\ell)$ is connected.

Proof. For every length vector $\ell$, there is a fibration $E_{d}(\ell) \rightarrow S^{d-1}$ whose fibre $C_{d}(\ell)$ is the configuration space of polygonal chains with segment lengths $l_{1}, \ldots, l_{n}$ (see Appendix A). It was shown in Proposition 2.7 of [21] that if $a_{n-3}(\ell)=0$, then the space $C_{d}(\ell)$ is $(d-2)$-connected. The claim of the Proposition follows using the homotopy exact sequence of the fibration $E_{d}(\ell) \rightarrow S^{d-1}$.

## Chapter 2

## Homology and Morse-Bott Theory

The main result of this chapter is a certain generalisation to the Morse-Bott case of the classical Morse lacunary principle. This result will be used in subsequent chapters to study the homology and the cohomology of the spaces $E_{d}(\ell)$.

### 2.1 A brief Exposition of the Morse Complex

The purpose of this section is to give a brief account of the construction of the Morse complex. We refer to [34] and to [37] for detailed expositions.

Let $M$ be a closed manifold. For a Morse function $f$ on $M$, define $C_{*}(f ; \mathbf{Z})$ as the free abelian group generated by the critical points of $f$, graded by their Morse index.

Let $\operatorname{Crit}(f)$ denote the set of critical points of $f$. Recall that a vector field $X$ is gradient-like with respect to $f$ if

$$
X(f)>0 \text { on } M-\operatorname{Crit}(f)
$$

and if, moreover, for every critical point $p$ of $f$ there exist local coordinates $\left(x_{1}, \ldots, x_{n}\right)$ near $p$, so that $x_{j}(p)=0$ for $j=1, \ldots, n$ and

$$
f\left(x_{1}, \ldots, x_{n}\right)=f(p)-\sum_{j=1}^{k} x_{j}^{2}+\sum_{j=k+1}^{n} x_{j}^{2}
$$

as well as

$$
X\left(x_{1}, \ldots, x_{n}\right)=-2 \sum_{j=1}^{k} x_{j} \frac{\partial}{\partial x_{j}}+2 \sum_{j=k+1}^{n} x_{j} \frac{\partial}{\partial x_{j}} .
$$

Here $n$ denotes the dimension of $M$ and $k$ the Morse index of the critical point $p$.

For $p, q \in \operatorname{Crit}(f)$, denote by $U_{p}(f)$ (respectively by $\left.S_{q}(f)\right)$ the unstable manifold at $p$ (respectively the stable manifold at $q$ ) of the flow of $-X$. We say that a vector field $X$ on $M$ is a Morse-Smale vector field adapted to $f$ if $X$ is gradient-like with respect to $f$ and if, moreover, all the intersections

$$
U_{p}(f) \cap S_{q}(f), p, q \in \operatorname{Crit}(f)
$$

are transverse. It is well-known that such a vector field exists for every Morse function (see e.g. [34], Theorem 2.27).

For each pair $p, q$ of critical points of $f$, elements of the space

$$
\widetilde{\mathcal{M}}(p, q)=U_{p}(f) \cap S_{q}(f)
$$

may be viewed as trajectories $\gamma: \mathbb{R} \rightarrow M$ of the flow of $-X$ satisfying

$$
\lim _{t \rightarrow-\infty} \gamma(t)=p \text { and } \lim _{t \rightarrow \infty} \gamma(t)=q
$$

For every element $\gamma \in \widetilde{\mathcal{M}}(p, q)$ and each $s \in \mathbb{R}$ the map

$$
\gamma_{s}: \mathbb{R} \rightarrow M, \gamma_{s}(t)=\gamma(s+t)
$$

is also an element of $\widetilde{\mathcal{M}}(p, q)$. Thus $\widetilde{\mathcal{M}}(p, q)$ is equipped with a free $\mathbb{R}$-action and one defines the space $\mathcal{M}(p, q)$ of unparametrised flow lines originating in $p$ and ending in $q$ as the quotient

$$
\mathcal{M}(p, q)=\widetilde{\mathcal{M}}(p, q) / \mathbb{R}
$$

If $X$ is a Morse-Smale vector field adapted to $f$, then the space $\mathcal{M}(p, q)$ is empty if $|p|-|q|-1<0$ and a manifold of dimension

$$
\operatorname{dim} \mathcal{M}(p, q)=|p|-|q|-1
$$

if $|p|-|q|-1 \geq 0$.

Choosing orientations of the unstable manifolds of all the critical points defines orientations of all the manifolds $\mathcal{M}(p, q)$. If $X$ is a Morse-Smale vector field adapted to $f$, then for every pair $p, q \in \operatorname{Crit}(f)$ with $|p|-|q|=1$, the space $\mathcal{M}(p, q)$ is compact. One defines

$$
\begin{equation*}
\partial: C_{*}(f ; \mathbf{Z}) \rightarrow C_{*-1}(f ; \mathbf{Z}) \tag{2.1}
\end{equation*}
$$

by

$$
\partial p=\sum_{|p|-|q|=1}|\mathcal{M}(p, q)| q .
$$

Here $|\mathcal{M}(p, q)|$ denotes the number of elements of $\mathcal{M}(p, q)$, counted with orientation. To demonstrate that $\partial^{2}=0$ and thus $\partial$ defines the structure of a chain complex on $C_{*}(f ; \mathbf{Z})$, one studies a natural compactification of the components $\mathcal{M}(p, q)$ with $|p|-|q|=2$.

If $H_{*}(f ; \mathbf{Z})$ denotes the homology of the complex $C_{*}(f ; \mathbf{Z})$, then there is an isomorphism

$$
\begin{equation*}
H_{*}(f ; \mathbf{Z}) \simeq H_{*}(M ; \mathbf{Z}) \tag{2.2}
\end{equation*}
$$

We mention some known extensions of the construction of the Morse complex $C_{*}(f ; \mathbf{Z})$. If one uses the flow of $X$ rather than the flow of $-X$, then, repeating the above steps in the construction of the complex $\left(C_{*}(f), \delta\right)$, one obtains a cochain complex $\left(C^{*}(f), d\right)$ whose cohomology is isomorphic to the cohomology $H^{*}(M ; \mathbf{Z})$ of $M$. If $M$ is compact but $\partial M \neq \emptyset$, then the complex $C_{*}(f ; \mathbf{Z})$ is well-defined if $d f \neq 0$ on the boundary of $M$ and if $\partial M$ coincides with the set of points of $M$ where $f$ attains its maximum. Moreover, in this case the isomorphism (2.2) continues to hold.

One finds in the literature several approaches which generalise the construction of the complex $C_{*}(f ; \mathbf{Z})$ to the case of Morse-Bott functions (see [2], 3], as well as Appendix A in (17).

### 2.2 A lacunary Principle for Morse-Bott Functions

In this section we recall the classical Morse lacunary principle and study a generalisation to the case of Morse-Bott functions.

Let $f$ be a Morse function on a compact manifold $M$. If $M$ has non-empty boundary, assume that $d f \neq 0$ on $\partial M$ and that $\partial M$ coincides with the set of points of $M$, where $f$ attains its maximum.

We say that $f$ is a lacunary Morse function if the indices of all the critical points of $f$ are multiples of some integer $k \geq 2$. A Morse function $f$ is called perfect if there are isomorphisms

$$
C_{*}(f ; \mathbf{Z}) \simeq H_{*}(M ; \mathbf{Z})
$$

of abelian groups.

The Morse lacunary principle states that every lacunary Morse function is perfect. This claim is readily confirmed using the picture of the Morse complex given in the previous section: in the case where $f$ is lacunary, the differential (2.1) vanishes identically for dimensional reasons and perfectness of $f$ follows from (2.2).

We now propose a generalisation of the lacunary principle to the Morse-Bott case. This generalisation is motivated by the special properties of the robot arm distance map that were demonstrated in Lemma 1.6.1.

We recall that a smooth function $f: M \rightarrow \mathbb{R}$ is called Morse-Bott if the set $\operatorname{Crit}(f)$ of critical points of $f$ is a disjoint union of submanifolds of $M$ and the restriction of the Hessian of $f$ to each connected component $C$ of $\operatorname{Crit}(f)$ is nondegenerate in normal directions. For every connected component $C \subset \operatorname{Crit}(f)$, denote by $\operatorname{ind}_{f}(C)$ the Morse-Bott index of $C$. A Morse-Bott function $f$ is called perfect if there are
isomorphisms

$$
\begin{equation*}
H_{*}(M ; \mathbf{Z}) \simeq \bigoplus_{C \subset \operatorname{Crit}(f)} H_{*-\operatorname{ind}_{f}(C)}(M ; \mathbf{Z}) \tag{2.3}
\end{equation*}
$$

of abelian groups. The direct sum on the right-hand side of $(2.3)$ is over the connected components $C$ of the set of critical points of $f$.

Definition 2.2.1. Let $f$ be a Morse-Bott function. We say that $f$ is lacunary if there exists an integer $k \geq 2$ so that the following conditions are satisfied:

1. The Morse-Bott index $\operatorname{ind}_{f}(C)$ of every connected component $C \subset \operatorname{Crit}(f)$ is a multiple of $k$.
2. The homology groups $H_{*}(C ; \mathbf{Z})$ of every component are free abelian and the non-trivial groups are concentrated in dimensions which are multiples of $k$.

Theorem 2.2.2 (A lacunary principle for Morse-Bott functions). Let $f$ be a smooth function on a compact manifold $M$. If $\partial M \neq \emptyset$, then assume that $d f \neq 0$ on $\partial M$ and that the boundary $\partial M$ coincides with the set of points of $M$ where $f$ attains its maximum.

If $f$ is lacunary in the sense of Definition 2.2.1, then $f$ is perfect. Thus in this case there are isomorphisms of abelian groups

$$
H_{*}(M ; \mathbf{Z}) \simeq \bigoplus_{C} H_{*-i n d_{f}(C)}(C ; \mathbf{Z})
$$

where the direct sum is over the connected components $C$ of the set of critical points of $f$.

Proof. Denote for $a \in \mathbb{R}$ by $M^{a}$ the preimage $M^{a}=f^{-1}(-\infty, a)$. We want to show that for every $a \in \mathbb{R}$, there is an isomorphism

$$
H_{*}\left(M^{a} ; \mathbf{Z}\right) \simeq \bigoplus_{f(C)<a} H_{*-\operatorname{ind}_{f}(C)}(C ; \mathbf{Z})
$$

If the interval $(-\infty, a)$ contains exactly one critical value of $f$, then existence of this isomorphism follows from the fact that the union of all the critical submanifolds $C$, for which $f(C)<a$, is a deformation retract of $M^{a}$. Assume now that the desired
isomorphism has been established for some $a \in \mathbb{R}$ and that for some $b>a$ there is exactly one critical value of $f$ in the interval $(a, b)$.

The unstable bundle of every critical submanifold $C$ is orientable since the cohomology group $H^{1}\left(C ; \mathbf{Z}_{2}\right)$ vanishes due to the second condition of Definition 2.2.1. Using excision and the Thom isomorphism theorem, it follows that

$$
\begin{equation*}
H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}\right) \simeq \bigoplus_{f(C) \in(a, b)} H_{*-\operatorname{ind}_{f}(C)}(C ; \mathbf{Z}) \tag{2.4}
\end{equation*}
$$

In particular, the non-trivial homology groups $H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}\right)$ are concentrated in dimensions which are multiples of $k$.

Arguing inductively, we can assume that the non-trivial groups $H_{*}\left(M^{a} ; R\right)$ lie in dimensions that are multiples of $k$. Then the homological exact sequence of the pair $\left(M^{b}, M^{a}\right)$ reduces to short exact sequences

$$
\begin{equation*}
0 \mapsto H_{*}\left(M^{a} ; \mathbf{Z}\right) \rightarrow H_{*}\left(M^{b} ; R\right) \rightarrow H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}\right) \rightarrow 0 \tag{2.5}
\end{equation*}
$$

Using (2.4) and the second assumption of Definition 2.2.1, the relative groups $H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}\right)$ are free abelian. Thus the short exact sequence 2.5 splits, yielding an isomorphism

$$
\begin{aligned}
H_{*}\left(M^{b} ; R\right) & \simeq H_{*}\left(M^{a} ; \mathbf{Z}\right) \oplus H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}\right) \\
& \simeq H_{*}\left(M^{a} ; \mathbf{Z}\right) \oplus \bigoplus_{f(C) \in(a, b)} H_{*-\operatorname{ind}_{f}(C)}(C ; \mathbf{Z}) .
\end{aligned}
$$

This completes the proof.

### 2.3 Identifying a Homology Basis

In this section we consider the case of a lacunary Morse-Bott function (see Definition 2.2.1) with the additional property that every component $C \subset \operatorname{Crit}(f)$ is homeomorphic to the sphere $S^{k}$. One concludes from Theorem 2.2 .2 that under this additional assumption each critical submanifold $C$ contributes two generators to the
homology of $M$, in dimensions $\operatorname{ind}_{f}(C)$ and $\operatorname{ind}_{f}(C)+k$. The following criterion can be used to identify these generators.

Theorem 2.3.1. Let $M$ be a compact manifold and $f: M \rightarrow \mathbb{R}$ a Morse-Bott function. If $\partial M \neq \emptyset$, then assume that $d f \neq 0$ on $\partial M$ and that $\partial M$ coincides with the set of points where $f$ attains its maximum.

Assume that $f$ is lacunary (see Definition 2.2.1) and that every component $C \subset$ $\operatorname{Crit}(f)$ is homeomorphic to the $k$-dimensional sphere. Moreover, suppose that for each component $C$ there are closed submanifolds

$$
V_{C}, W_{C} \subset M
$$

with the following properties:

1. $\operatorname{dim} W_{C}=\operatorname{ind}_{f}(C)+k, C \subset W_{C}$ and $f(p)>f(q)$ for $p \in C, q \in W_{C}-C$.
2. $C \subset W_{C}$ is a nondegenerate critical submanifold of the restriction of $f$ to $W_{C}$.
3. $\operatorname{dim} V_{C}=\operatorname{ind}_{f}(C)$ and $V_{C} \subset W_{C}$. Furthermore $C$ and $V_{C}$ intersect transversally as submanifolds of $W_{C}$ in one point.

Then the collection of the homology classes $\left\{\left[V_{C}\right],\left[W_{C}\right]\right\}$, where $C$ is a connected component of $\operatorname{Crit}(f)$, forms a basis of $H_{*}\left(M ; \mathbf{Z}_{2}\right)$.

Proof. We use notation from the proof of Theorem 2.2.2. We want to show that for every $a \in \mathbb{R}$, there is a basis of $H_{*}\left(M^{a} ; \mathbf{Z}_{2}\right)$ consisting of the classes $\left[V_{C}\right]$, $\left[W_{C}\right]$ for $f(C)<a$.

We assume first that the interval $(-\infty, a)$ contains a single critical value of $f$. Then there is a deformation retraction of $M^{a}$ onto the union of those components $C$ of the set of critical points of $f$, where $f$ attains its minimum. For every such component $C$,

$$
W_{C}=C \text { and } V_{C}=\{p t\} \in C .
$$

Since $C$ is homeomorphic to the sphere, the homology classes of $W_{C}$ and $V_{C}$ form a basis of $H_{*}\left(C ; \mathbf{Z}_{2}\right)$. It follows that the classes $\left[V_{C}\right],\left[W_{C}\right]$ with $f(C)<a$ form a
homology basis of $H_{*}\left(M^{a} ; \mathbf{Z}_{2}\right)$.

Suppose now that the statement has been proved for some $a \in \mathbb{R}$ and that the interval $(a, b)$ contains a single critical value of $f$. We want to show that there is a basis of $H_{*}\left(M^{b} ; \mathbf{Z}_{2}\right)$ consisting of the classes $\left[V_{C}\right],\left[W_{C}\right]$ for $f(C)<b$. By the proof of Theorem 2.2.2, there is an isomorphism

$$
\begin{equation*}
H_{*}\left(M^{b} ; \mathbf{Z}_{2}\right) \simeq H_{*}\left(M^{a} ; \mathbf{Z}_{2}\right) \oplus H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}_{2}\right) \tag{2.6}
\end{equation*}
$$

Thus it suffices to show that the relative homology classes [ $W_{C}, W_{C} \cap M^{a}$ ] and [ $\left.V_{C}, V_{C} \cap M^{a}\right]$, where $f(C) \in(a, b)$, form a basis of $H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}_{2}\right)$. Using excision, the deformation retraction given by the negative gradient flow of $f$ and the Thom isomorphism,

$$
\begin{gather*}
H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}_{2}\right) \simeq \bigoplus_{f(C) \in(a, b)} H_{*}\left(W_{C}, W_{C} \cap M^{a} ; \mathbf{Z}_{2}\right)  \tag{2.7}\\
\simeq \bigoplus_{f(C) \in(a, b)} H_{*-\operatorname{ind}_{f}(C)}\left(C ; \mathbf{Z}_{2}\right) . \tag{2.8}
\end{gather*}
$$

The images under the composition of the two isomorphisms (2.7) and (2.8) of the classes $\left[W_{C}, W_{C} \cap M^{a}\right]$ and $\left[V_{C}, V_{C} \cap M^{a}\right]$ are respectively $\left[W_{C} \cap C\right]=[C]$ and $\left[V_{C} \cap\right.$ $C]=[p t]$. Since every critical submanifold $C$ is homeomorphic to the sphere, these images form a basis of $H_{*}\left(C ; \mathbf{Z}_{2}\right)$. Thus the classes [ $\left.W_{C}, W_{C} \cap M^{a}\right]$ and $\left[V_{C}, V_{C} \cap M^{a}\right]$, where $f(C) \in(a, b)$, form a basis of $H_{*}\left(M^{b}, M^{a} ; \mathbf{Z}_{2}\right)$. This completes the proof.

If in the situation of Theorem 2.3 .1 the submanifolds $V_{C}, W_{C} \subset M$ are all oriented, then the claim of the proposition continues to hold when homology with $\mathbf{Z}_{2}$-coefficients is replaced by integral homology:

Corollary 2.3.2. Suppose that in addition to the assumptions of Proposition 2.3.1, for every component $C \subset C r i t(f)$ the submanifolds $V_{C}, W_{C} \subset M$ are oriented. Then the collection of the homology classes $\left\{\left[V_{C}\right],\left[W_{C}\right]\right\}$, where $C \subset \operatorname{Crit}(f)$ is a connected component, forms a free basis of $H_{*}(M ; \mathbf{Z})$.

Proof. It suffices to show that under these additional assumptions the claim of the inductive step of the proof of Theorem 2.3.1 also holds in the case of integral homology.

Since the unstable bundle of each critical submanifold is orientable, we may replace in (2.7) and 2.8) the coefficient group $\mathbf{Z}_{2}$ by $\mathbf{Z}$. We fix an orientation of the normal bundle to $C$ in $W_{C}$. Together with the given orientations of the manifolds $W_{C}$ and $V_{C}$, this defines orientations of the intersections $W_{C} \cap C=C$ and $V_{C} \cap C=$ $\{p t\}$, so that the images under the composition of (2.7) and (2.8) of the classes $\left[W_{C}, W_{C} \cap M^{a}\right] \in H_{\operatorname{ind}_{f}(C)+k}\left(M^{b}, M^{a} ; \mathbf{Z}\right)$ and $\left[V_{C}, V_{C} \cap M^{a}\right] \in H_{\operatorname{ind}_{f}(C)}\left(M^{b}, M^{a} ; \mathbf{Z}\right)$ generate $H_{k}(C ; \mathbf{Z})$ respectively $H_{0}(C ; \mathbf{Z})$. This completes the proof.

## Chapter 3

## Homology of Spaces of Polygons

In this chapter we study the homology groups of the spaces $E_{d}(\ell)$. We explicitly compute the $\mathbf{Z}_{2}$-Betti numbers, show that the integral homology groups are torsionfree when $d$ is even and find a combinatorial criterion for the existence of torsion elements in the integral homology groups in the case where $d$ is odd. These results cover both generic and non-generic length vectors. We also compute the asymptotic behaviour of the homotopy groups and of the average Betti numbers of the spaces $E_{d}(\ell)$ as the number $n$ of edges becomes large.

### 3.1 The Homology Groups

By the first part of Proposition 1.5.2, there is a homeomorphism $E_{2}(\ell) \simeq S^{1} \times M_{\ell}$, where $M_{\ell}=E_{2}(\ell) / S O(2)$ is the space of planar polygons, viewed up to translations as well as rotations. The integral homology groups of the spaces $M_{\ell}$ were computed in [15. In this section we present results concerning the homology of the spaces $E_{d}(\ell)$ in the case $d>2$.

In Section 1.4, we defined the combinatorial quantities $a_{k}(\ell)$ and $b_{k}(\ell)$ as the numbers of subsets $J \subset\{1, \ldots, n\}$ of cardinality $|J|=k+1$ which contain the index of a maximal entry of the length vector $\ell$ and are short respectively median with respect to $\ell$.

Theorem 3.1.1. Let $d>2$. The non-vanishing $\mathbf{Z}_{2}$-Betti numbers of the spaces $E_{d}(\ell)$ are

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=a_{k}(\ell)+b_{k}(\ell)+a_{k-1}(\ell)+b_{k-1}(\ell)
$$

for $k=0, \ldots, n-2$ as well as

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=a_{n-1-k}(\ell)+a_{n-2-k}(\ell)
$$

for $k=1, \ldots, n-1$.

The proof, given in Section 3.5, relies on the Morse-Bott lacunary principle established in Chapter 2.

It follows from the computation in [15] of the integral homology groups of the spaces $M_{\ell}$, the homeomorphism $E_{2}(\ell) \simeq S^{1} \times M_{\ell}$ and the Künneth theorem that the integral homology groups of the spaces $E_{2}(\ell)$ are free abelian. Concerning the integral homology of the spaces $E_{d}(\ell)$ for $d>2$, we will show:

Theorem 3.1.2. Let $d>2$.

1. The non-vanishing homology groups $H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ are concentrated in dimensions

$$
p=(d-1) k, 0 \leq k \leq n-2
$$

and

$$
p=(d-1) k-1,1 \leq k \leq n-1 .
$$

2. The groups $H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}\right), 0 \leq k \leq n-2$ are free abelian.

Next, we study the question of the existence of torsion elements in the groups $H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right), 1 \leq k \leq n-1$.

Theorem 3.1.3. If $d$ is even, then the groups

$$
H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right), 1 \leq k \leq n-1
$$

are free abelian.

Together with Theorem 3.1.2, it follows that all the integral homology groups of the space $E_{d}(\ell)$ are torsion-free if $d$ is even. Using the universal coefficient theorem, we obtain:

Corollary 3.1.4. If $d>2$ is even, then the Betti numbers

$$
b_{p}\left(E_{d}(\ell)\right)=\operatorname{rk} H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)
$$

coincide with the $\mathbf{Z}_{2}$-Betti numbers given in Theorem 3.1.1.

The results of Chapter 1 show that if $d$ is odd, then the homology groups of the form $H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ in general contain torsion elements. For example, for $d=3$ and $\ell=(1,1,1)$ one concludes from the first part of Proposition 1.2 .2 that

$$
H_{1}\left(E_{3}(\ell) ; \mathbf{Z}\right) \simeq H_{1}\left(T^{1} S^{2} ; \mathbf{Z}\right) \simeq H_{1}(S O(3) ; \mathbf{Z}) \simeq \mathbf{Z}_{2}
$$

We will show that in the case of odd $d$, the existence of torsion elements can be detected by an explicit combinatorial criterion:

Theorem 3.1.5. Assume that $d$ is odd. Let $m \in\{1, \ldots, n\}$ be the index of any maximal entry of the length vector $\ell$.

The following conditions are equivalent:

1. There are torsion elements in the homology group $H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$, where $k \in\{1, \ldots, n-2\} ;$
2. There exists a subset $J \subset\{1, \ldots, n\}$ with the following properties:
(a) $m \notin J,|J|=k+1$ and $J$ is long respect to $\ell$.
(b) There exist indices $i, j \in J, i \neq j$, so that the set $I=J-\{i, j\} \cup\{m\}$ is either short or median with respect to $\ell$.

In many cases Theorem 3.1.5 can be used to rule out the existence of torsion elements in the integral homology groups of the space $E_{d}(\ell)$. For example, suppose that $l_{m} \geq l_{i}+l_{j}$ for all of indices $i, j \neq m$, in other words that there is an edge which is no shorter than any two other edges combined.

Using the formula

$$
\ell_{I}=\ell_{J}+2\left(l_{m}-l_{i}-l_{j}\right),
$$

we see that for every long subset $J \subset\{1, \ldots, n\}$ with $m \notin J$ and every pair $i, j \in J$ the set $I=J-\{i, j\} \cup\{m\}$ is again long with respect to $\ell$. Thus in this case there are no subsets $J \subset\{1, \ldots, n\}$ that satisfy the conditions of the second part of Theorem 3.1.5. One concludes:

Corollary 3.1.6. Suppose that there is an edge which is no shorter than any two other edges combined: there exists an index $m \in\{1, \ldots, n\}$ so that

$$
l_{m} \geq l_{i}+l_{j} \text { for all } i, j \neq m
$$

Then for every $d \geq 2$ the integral homology groups of the space $E_{d}(\ell)$ are free abelian. Thus if $d>2$, then the Betti numbers $b_{p}\left(E_{d}(\ell)\right)=r k H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ coincide with the $\mathbf{Z}_{2}$-Betti numbers computed in Theorem 3.1.1.

The proofs of Theorems 3.1.2, 3.1.3 and 3.1.5 are given in Section 3.6.

### 3.2 Examples and Applications

We now discuss some applications of the results given in the preceding section.

By Theorem 3.1.1, the space $E_{d}(\ell)$ is connected if $d>2$ and the homology groups $H_{p}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ with $1 \leq p<d-2$ vanish. This is consistent with Corollary 1.6.9 which states that for $d>2$ the space $E_{d}(\ell)$ is $(d-3)$-connected.

The first possible non-vanishing $\mathbf{Z}_{2}$-Betti number of positive dimension is

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{d-2}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=a_{n-3}(\ell)+a_{n-2}(\ell) .
$$

By Definition 1.4.1, $a_{n-2}(\ell)$ is the number of subsets $J \subset\{1, \ldots, n\}$ which contain the index $m$ of a maximal entry of $\ell$, are short with respect to $\ell$ and have cardinality $|J|=n-1$. Since $n \geq 3$, the number $a_{n-2}(\ell)$ vanishes. As was remarked in 1.6.7, the
number $a_{n-3}(\ell)$ can only assume the values 0 and 1 and the condition $a_{n-3}(\ell)=1$ implies that $\ell$ is generic and determines the chamber of $\ell$ uniquely up to permutation of the entries. Using Proposition 1.6.6, one concludes:

Proposition 3.2.1. If $d>2$, then the following conditions are equivalent:

1. The homology group $H_{d-2}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ is non-trivial;
2. The number $a_{n-3}(\ell)$ is equal to one;
3. The length vector $\ell$ is generic and there is a diffeomorphism

$$
E_{d}(\ell) \simeq\left(S^{d-1}\right)^{n-3} \times T^{1} S^{d-1}
$$

Assume now that $a_{n-3}(\ell)=0$. It follows from Proposition 1.6.10 that in this case the integral homology group $H_{d-2}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ is trivial. Using Theorem 3.1.1, the second part of Theorem 3.1 .2 and the universal coefficient theorem, we conclude that for $d>2$ the homology group $H_{d-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ is free abelian of $\operatorname{rank} a_{1}(\ell)+b_{1}(\ell)+$ $a_{0}(\ell)+b_{0}(\ell)$. By the first part of Proposition 1.5.1, $a_{0}(\ell)+b_{0}(\ell)=1$ if the space $E_{d}(\ell)$ is non-empty. Combining Proposition 1.6 .10 with the Hurewicz theorem, we find:

Proposition 3.2.2. Let $d>2$. If $a_{n-3}(\ell)=0$ and $E_{d}(\ell) \neq \emptyset$, then the homotopy group $\pi_{d-1}\left(E_{d}(\ell)\right)$ is free abelian of rank

$$
a_{1}(\ell)+b_{1}(\ell)+1 .
$$

Proposition 3.2 .2 becomes false for $d=2$. For example, consider the case $n=5$, $\ell=(1,1,1,1,1)$. The condition $a_{2}(\ell)=0$ is satisfied. On the other hand, it follows from the second part of Proposition 1.5 .2 and Theorem 2 in [27] that there are homeomorphisms

$$
E_{2}(\ell) \simeq S^{1} \times M_{\ell} \simeq S^{1} \times \Sigma_{4},
$$

where $\Sigma_{4}$ is the closed oriented surface of genus four. Thus in this case the fundamental group $\pi_{1}\left(E_{2}(\ell)\right)$ is not free abelian.

It is known that for non-generic length vectors $\ell$ the planar polygon spaces $M_{\ell}$ are manifolds with finitely many singular points corresponding to median subsets $J \subset\{1, \ldots, n\}([7]$, Theorem 1.6). Let us use Theorem 3.1.1 to study the question whether the space $E_{d}(\ell)$ can be a manifold if $\ell$ is non-generic.

By Theorem 3.1.1, the greatest possible non-vanishing $\mathbf{Z}_{2}$-Betti number of the space $E_{d}(\ell)$ is

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1)(n-1)-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=a_{0}(\ell) .
$$

The number $a_{0}(\ell)$ is either zero (if the one-element set $\{m\}$ consisting of the index of a maximal entry of $\ell$ is long or median with respect to $\ell$ ) or one (if $\{m\}$ is short with respect to $\ell$ ). If $a_{0}(\ell)=0$, then either $E_{d}(\ell)=\emptyset$ or there is a homeomorphism $E_{d}(\ell) \simeq S^{d-1}$. On the other hand, Theorem 3.1.1 shows that in the case $d>2$ the space $E_{d}(\ell)$ fails to satisfy Poincaré duality for every non-generic length vector $\ell$ with $a_{0}(\ell)=1$. Indeed, from the formulae for the $\mathbf{Z}_{2}$-Betti numbers we see that the condition

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1)(n-k-1)-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

is satisfied for all $k=1, \ldots, n-2$ if and only if all the numbers $b_{k}(\ell)$ vanish. We conclude:

Proposition 3.2.3. For every non-generic length vector $\ell$ with $a_{0}(\ell)=1$ the space $E_{d}(\ell)$ is not a topological manifold.

Let us now apply Theorem 3.1.1 to compute the Euler characteristic of the space $E_{d}(\ell)$. Recall from Section 1.3 that $\mathcal{M}(\ell)$ denotes the set of all subsets $J \subset$ $\{1, \ldots, n\}$ that are median with respect to the length vector $\ell$.

Proposition 3.2.4. The Euler characteristic of the space $E_{d}(\ell)$ is given by

$$
\chi\left(E_{d}(\ell)\right)=\left\{\begin{array}{cl}
|\mathcal{M}(\ell)| & \text { if } d \text { is odd } \\
0 & \text { if } d \text { is even }
\end{array}\right.
$$

In particular, for every generic length vector $\ell$ the Euler characteristic of the space $E_{d}(\ell)$ is zero.

Proof. The Euler characteristic of $E_{2}(\ell)$ vanishes since this space is homeomorphic to the product $S^{1} \times M_{\ell}$ by the first part of Proposition 1.5.2.

Suppose that $d>2$ is even. Applying Theorem 3.1.1.

$$
\begin{aligned}
\chi\left(E_{d}(\ell)\right) & =\sum_{k=0}^{n-2}(-1)^{k}\left(a_{k}(\ell)+b_{k}(\ell)+a_{k-1}(\ell)+b_{k-1}(\ell)\right) \\
& +\sum_{k=1}^{n-1}(-1)^{k-1}\left(a_{n-1-k}(\ell)+a_{n-2-k}(\ell)\right) .
\end{aligned}
$$

Since $a_{-1}(\ell)=b_{-1}(\ell)=0$ and $a_{n-2}(\ell)=b_{n-2}(\ell)=0$, both sums vanish and thus $\chi\left(E_{d}(\ell)\right)=0$.

In the case where $d$ is odd, one computes

$$
\begin{aligned}
\chi\left(E_{d}(\ell)\right) & =\sum_{k=0}^{n-2}\left(a_{k}(\ell)+b_{k}(\ell)+a_{k-1}(\ell)+b_{k-1}(\ell)\right) \\
& -\sum_{k=1}^{n-1}\left(a_{n-1-k}(\ell)+a_{n-2-k}(\ell)\right) \\
& =2 \sum_{k=0}^{n-3} b_{k}(\ell)=|\mathcal{M}(\ell)| .
\end{aligned}
$$

Here we used the fact that the number $b_{n-2}(\ell)$ is zero as every subset $J \subset\{1, \ldots, n\}$ which contains the index of a maximal entry and has cardinality $|J|=n-1$ must be long with respect to $\ell$. The sum $\sum_{k=0}^{n-3} b_{k}(\ell)$ is the number of all median sets containing the index of a maximal entry and is thus equal to $\frac{1}{2}|\mathcal{M}(\ell)|$.

Let us give a second, more direct proof of Proposition 3.2.4. The proof relies on the well-known fact that the Euler characteristic of a space equipped with a continuous $S^{1}$-action coincides with the Euler characteristic of the set of fixed points of the action (this is a consequence of the Lefschetz fixed point theorem; a proof can be found in 31, Theorem 5.5).

Fix a two-dimensional subspace $E \subset \mathbb{R}^{d}$ and an orientation of $E$. Consider the $S^{1}$-action on $\mathbb{R}^{d}$ where every element of $S^{1}$ acts by a linear map that rotates each vector in $E$ in the positive direction and fixes every vector which is orthogonal to
$E$. We study the induced $S^{1}$-action on $E_{d}(\ell)$. If $d=2$, then this action is free and thus

$$
\begin{equation*}
\chi\left(E_{2}(\ell)\right)=0 . \tag{3.1}
\end{equation*}
$$

The set of fixed points of the $S^{1}$-action on $E_{3}(\ell)$ consists exactly of those polygons (viewed up to translations), where all the edges are perpendicular to $E$. Since every polygon of this type corresponds to a unique median subset of $\{1, \ldots, n\}$, the number of fixed points is $|\mathcal{M}(\ell)|$. Thus

$$
\begin{equation*}
\chi\left(E_{3}(\ell)\right)=|\mathcal{M}(\ell)| . \tag{3.2}
\end{equation*}
$$

For $d>3$, the set of fixed points of the action may be identified with $E_{d-2}(\ell)$ and thus

$$
\begin{equation*}
\chi\left(E_{d}(\ell)\right)=\chi\left(E_{d-2}(\ell)\right) \text { for } d>3 \tag{3.3}
\end{equation*}
$$

Equations (3.1)-(3.3) imply that $\chi\left(E_{d}(\ell)\right)=\chi\left(E_{2}(\ell)\right)=0$ if $d$ is even and $\chi\left(E_{d}(\ell)\right)=$ $\chi\left(E_{3}(\ell)\right)=|\mathcal{M}(\ell)|$ for $d$ odd.

We now evaluate the $\mathbf{Z}_{2}$-Betti numbers in the cases of Propositions 1.6.3, 1.6.5 and 1.6.6.

Example 3.2.5. Consider the case of a massive edge (see Proposition 1.6.3): assume that the length vector $\ell$ is generic and that there is a maximal short one-element subset $\{m\} \subset\{1, \ldots, n\}$. In this case $a_{0}(\ell)=1$ and $a_{k}(\ell)=0$ for $k>0$. The numbers $b_{k}(\ell)$ vanish. Thus by Theorem 3.1.1 the non-zero $\mathbf{Z}_{2}$-Betti numbers are

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{0}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1)(n-1)-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=1
$$

and

$$
\operatorname{dim}_{\mathbf{Z}_{2}} H_{d-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1)(n-2)-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=1
$$

This can be checked using Proposition 1.6.3. Namely, for $n>3$ there is a diffeomorphism

$$
E_{d}(\ell) \simeq S^{(d-1)(n-2)-1} \times S^{d-1}
$$

and the Betti numbers are as indicated above.

If $n=3$, then by Proposition 1.6.3,

$$
E_{d}(\ell) \simeq T^{1} S^{d-1}
$$

The homology groups of the latter space are easily computed from the Gysin exact sequence (see e.g. Section 4.D in [19)

$$
\cdots \rightarrow H_{p+(d-1)}\left(T^{1} S^{d-1} ; \mathbf{Z}\right) \rightarrow H_{p+(d-1)}\left(S^{d-1} ; \mathbf{Z}\right) \rightarrow H_{p}\left(S^{d-1} ; \mathbf{Z}\right) \rightarrow \ldots
$$

Here the map $H_{p+(d-1)}\left(S^{d-1} ; \mathbf{Z}\right) \rightarrow H_{p}\left(S^{d-1} ; \mathbf{Z}\right)$ is the cap product with the Euler class of the tangent bundle of $S^{d-1}$; this class is zero if $d$ is even and is given by twice the generator of $H^{d-1}\left(S^{d-1} ; \mathbf{Z}\right)$ if $d$ is odd. Thus

$$
H_{d-1}\left(T^{1} S^{d-1} ; \mathbf{Z}\right) \simeq \begin{cases}0 & \text { if } d \text { is odd }  \tag{3.4}\\ \mathbf{Z} & \text { if } d \text { is even. }\end{cases}
$$

and

$$
H_{d-2}\left(T^{1} S^{d-1} ; \mathbf{Z}\right) \simeq \begin{cases}\mathbf{Z}_{2} & \text { if } d \text { is odd }  \tag{3.5}\\ \mathbf{Z} & \text { if } d \text { is even }\end{cases}
$$

Applying the universal coefficient theorem,

$$
\begin{equation*}
H_{d-2}\left(T^{1} S^{d-1} ; \mathbf{Z}_{2}\right) \simeq H_{d-1}\left(T^{1} S^{d-1} ; \mathbf{Z}_{2}\right) \simeq \mathbf{Z}_{2} \tag{3.6}
\end{equation*}
$$

We see that for $n=3$ the $\mathbf{Z}_{2}$-Betti numbers of the space $E_{d}(\ell)$ agree with the formulae of Theorem 3.1.1.

Example 3.2.6. Let us investigate how the $\mathbf{Z}_{2}$-Betti numbers of the spaces $E_{d}(\ell)$ change under the operation of inserting a small edge (see Proposition 1.6.5). Let $\ell$ be a generic length vector, $0<\varepsilon<[\ell]$ and $\ell^{\prime}=(\varepsilon, \ell)$. For a subset $J \subset\{1, \ldots, n\}$, denote by $\widehat{J}$ the set $\widehat{J}=\{j+1: j \in J\}$. Then

$$
J \in \mathcal{L}(\ell) \Longleftrightarrow \widehat{J} \in \mathcal{L}\left(\ell^{\prime}\right) \Longleftrightarrow \widehat{J} \cup\{1\} \in \mathcal{L}\left(\ell^{\prime}\right)
$$

We conclude that

$$
a_{k}\left(\ell^{\prime}\right)=a_{k-1}(\ell)+a_{k}(\ell)
$$

for $k=1, \ldots, n-1$. The numbers $b_{k}(\ell)$ and $b_{k}\left(\ell^{\prime}\right)$ are all zero as $\ell$ and $\ell^{\prime}$ are generic.

Using the Künneth theorem, we see that the formulae of Theorem 3.1.1 are consistent with the diffeomorphism

$$
E_{d}\left(\ell^{\prime}\right) \simeq S^{d-1} \times E_{d}(\ell)
$$

established in Proposition 1.6.5.
Example 3.2.7. We now consider the case of a massive triangle (see Proposition 1.6.6). Using Proposition 1.5.3, we can assume without loss of generality that $\ell$ is ordered. In this case existence of a massive triangle means that the two-element subset $\{n-2, n-1\} \subset\{1, \ldots, n\}$ is long with respect to $\ell$.

Under the above assumptions, $a_{k}(\ell)$ is the number of subsets $J \subset\{1, \ldots, n\}$ so that $n \in J, n-2 \notin J, n-1 \notin J$ and $|J|=k+1$. We conclude that

$$
a_{k}(\ell)=\binom{n-3}{k}
$$

The numbers $b_{k}(\ell)$ vanish. Using Theorem 3.1.1, we find that

$$
\begin{equation*}
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=\binom{n-2}{k} \tag{3.7}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)=\binom{n-2}{k-1} \tag{3.8}
\end{equation*}
$$

for $k=1, \ldots, n-2$. On the other hand, by Proposition 1.6.6,

$$
E_{d}(\ell) \simeq\left(S^{d-1}\right)^{n-3} \times T^{1} S^{d-1}
$$

Computing the $\mathbf{Z}_{2}$-homology groups of this latter space with the help of the Künneth theorem and $(3.6)$, one confirms formulae $(3.7)$ and $(3.8)$.

We now verify the criterion of Theorem 3.1.5 in the cases of Examples 3.2.5, 3.2.6 and 3.2.7.

Assume that there is a massive edge (see Proposition 1.6 .3 and Example 3.2.5). We distinguish between the two cases $n=3$ and $n>3$. In the latter case there are no sets $J$ as indicated in the second part of Theorem 3.1.5 the only short subset $J \subset\{1, \ldots, n\}$ with $m \in J$ is $J=\{m\}$ and every two-element set $\{i, j\}$ with
$i, j \neq m$ is short. Thus by Theorem 3.1.5 the homology groups $H_{*}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ are torsion-free. This agrees with the diffeomorphism

$$
E_{d}(\ell) \simeq S^{(d-1)(n-2)-1} \times S^{d-1}
$$

established in Proposition 1.6.3. If $n=3$, then the two-element set $J=\{1,2,3\}-$ $\{m\}$ obtained from the index set $\{1,2,3\}$ by removing the index $m$ of any maximal entry of $\ell$ satisfies both conditions of the second part of Theorem 3.1.5. Thus if $n=3$ and $d$ is odd, then the homology group $H_{d-2}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ must contain torsion elements. This can be checked as follows: by Proposition 1.6.6,

$$
E_{d}(\ell) \simeq T^{1} S^{d-1}
$$

If $d$ is odd, then $H_{d-2}\left(T^{1} S^{d-1} ; \mathbf{Z}\right) \simeq \mathbf{Z}_{2}$ by 3.5).

Consider now the operation of inserting a small edge (see Proposition 1.6 .5 and Example 3.2.6). Let $\ell$ be generic and let $0<\varepsilon<[\ell]$. The diffeomorphism

$$
E_{d}(\varepsilon, \ell) \simeq S^{d-1} \times E_{d}(\ell)
$$

established in Proposition 1.6.5 implies that the integral homology groups of the space $E_{d}(\varepsilon, \ell)$ contain torsion elements if and only if so do the integral homology groups of the space $E_{d}(\ell)$. This is consistent with Theorem 3.1.5, since the existence of subsets $J$ as described in part two of this Theorem is simultaneous for $\ell$ and for $\ell^{\prime}=(\varepsilon, \ell)$.

Finally, we verify the statement of Theorem 3.1 .5 in the case of a massive triangle. Assume that $\ell$ is ordered and $a_{n-3}(\ell)=1$ (see Proposition 1.6.6). Then the two-element set $\{n-2, n-1\}$ is long with respect to $\ell$. It follows that every subset $J \subset\{1, \ldots n\}$ with $|J|=k+1, n-2 \in J, n-1 \in J$ and $n \notin J$ satisfies both assumptions of the second part of Theorem 3.1.5, $J$ is long and the set

$$
I=J-\{n-2, n-1\} \cup\{n\}
$$

is short. Applying Theorem 3.1.5, we conclude that if $d$ is odd, then every homology group $H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right), 1 \leq k \leq n-2$ contains torsion elements. This can be
confirmed using the diffeomorphism

$$
E_{d}(\ell) \simeq\left(S^{d-1}\right)^{n-3} \times T^{1} S^{d-1}
$$

the Künneth Theorem and (3.5).

### 3.3 The equilateral Case

In this section we consider the important special case of equilateral polygons. Homology groups of spaces of equilateral planar polygons were studied in [25] and in [26], see also [15]. For $d>2$ we obtain the following result:

Proposition 3.3.1. Let $d>2$ and assume that $l_{i}=l_{j}$ for all $i, j=1, \ldots, n$. Denote by $r=\left\lfloor\frac{n}{2}\right\rfloor$ the largest integer with $2 r \leq n$.

1. The non-vanishing homology groups $H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ with $p \neq(d-1) r-1,(d-1) r$ are free abelian and concentrated in dimensions

$$
p=(d-1) k, 0 \leq 2 k \leq n-2
$$

and

$$
p=(d-1) k-1, n<2 k \leq 2 n-2 .
$$

Their ranks are

$$
r k H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}\right)=\binom{n}{k}, 0 \leq 2 k \leq n-2
$$

and

$$
r k H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)=\binom{n}{k+1}, n<2 k \leq 2 n-2 .
$$

2. If $d$ is even, then the groups $H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ and $H_{(d-1) r}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ are free abelian and their ranks are as follows. If $n=2 r+1$ is odd, then

$$
r k H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)=r k H_{(d-1) r}\left(E_{d}(\ell) ; \mathbf{Z}\right)=\binom{2 r}{r+1} .
$$

If $n=2 r$ is even, then

$$
r k H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)=\binom{2 r-1}{r+1}
$$

and

$$
r k H_{(d-1) r}\left(E_{d}(\ell) ; \mathbf{Z}\right)=\binom{2 r-1}{r} .
$$

Proof. In the equilateral case a subset $J \subset\{1, \ldots, n\}$ is short (respectively long or median) with respect to $\ell$ if and only if its cardinality satisfies $2|J|<n$ (respectively $2|J|>n$ or $2|J|=n)$. This allows to express the numbers $a_{k}(\ell)$ and $b_{k}(\ell)$ as binomial coefficients:

$$
a_{k}(\ell)=\left\{\begin{array}{cl}
\binom{n-1}{k} & \text { if } 2(k+1)<n, \\
0 & \text { if } 2(k+1) \geq n
\end{array}\right.
$$

and

$$
b_{k}(\ell)=\left\{\begin{array}{cl}
\binom{n-1}{k} & \text { if } 2(k+1)=n \\
0 & \text { if } 2(k+1) \neq n
\end{array}\right.
$$

Every subset $J \subset\{1, \ldots, n\}$ satisfying the conditions of the second part of Theorem 3.1.5 must have cardinality $|J|=r$. Thus by Theorems 3.1.2 and 3.1.5 all groups $H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ except for possibly $H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ are torsion-free. Applying the universal coefficient theorem for homology, one finds that for all $d>2$ the Betti numbers $b_{p}\left(E_{d}(\ell)\right)$ with $p \neq(d-1) r,(d-1) r-1$ coincide with the $\mathbf{Z}_{2}$-Betti numbers computed in Theorem 3.1.1. Substituting the above expressions for $a_{k}(\ell)$ and $b_{k}(\ell)$ into the formulae of Theorem 3.1.1, we obtain the first assertion.

If $d$ is even, then by Theorem 3.1 .3 the remaining group $H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ is free abelian as well. Thus in this case

$$
b_{(d-1) r}\left(E_{d}(\ell)\right)=\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) r}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

and

$$
b_{(d-1) r-1}\left(E_{d}(\ell)\right)=\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

by the universal coefficient theorem. The second assertion now follows from the formulae of Theorem 3.1.1.

Proposition 3.3.1 computes the integral homology groups of the spaces $E_{d}(\ell)$ in the equilateral case with the exception of the groups

$$
H_{(d-1) r}\left(E_{d}(\ell) ; \mathbf{Z}\right) \text { and } H_{(d-1) r-1}\left(E_{d}(\ell) ; \mathbf{Z}\right),
$$

where $r=\left\lfloor\frac{n}{2}\right\rfloor$ and $d$ is odd.

### 3.4 The Topology of random Polygons

Due to the possible existence of torsion elements in the groups $H_{*}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ when $d$ is odd, the Betti numbers $b_{p}\left(E_{d}(\ell)\right)=\mathrm{rk} H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ are in general different from the $\mathbf{Z}_{2}$-Betti numbers computed in Theorem 3.1.1. As we demonstrate in this section, the problem of computing the integral homology groups of the spaces $E_{d}(\ell)$ simplifies considerably in the setting of random linkages. Remarkably, the asymptotic values of the expectations of the Betti numbers can be computed explicitly. Before stating this result, we recall the main idea of the study of random linkages. We refer to [8] for a more detailed exposition.

It follows from Definition 1.1 .1 that for every $\tau>0$, the space $E_{d}(\tau \ell)$ obtained by rescaling the entries of the length vector $\ell \in \mathbb{R}_{>0}^{n}$ by the parameter $\tau$ can be identified with $E_{d}(\ell)$. Thus we can also parametrize the space of polygons by elements of the open unit simplex

$$
\Delta^{n-1}=\left\{\left(l_{1}, \ldots, l_{n}\right) \in \mathbb{R}_{>0}^{n}: \sum_{j=1}^{n} l_{j}=1\right\}
$$

The heuristic idea that in applications polygons with different edge lengths may be encountered with different probability can now be made precise as follows.

We view $\ell$ as a random variable characterized by a probability measure $\nu_{n}$ on the unit simplex $\Delta^{n-1}$. Topological invariants of the spaces $E_{d}(\ell)$ are now random functions and we are interested in their asymptotic behaviour as the number $n$ of edges becomes large. In this section, the asymptotic behaviour for large $n$ of the homotopy groups and of the expected Betti numbers of the spaces $E_{d}(\ell)$ is determined in the simplest case where $\nu_{n}$ is the normalized Lebesgue measure on $\Delta^{n-1}$, that is when

$$
\nu_{n}(A)=\frac{\operatorname{vol}(A)}{\operatorname{vol}\left(\Delta^{n-1}\right)}
$$

for every measurable subset $A \subset \Delta^{n-1}$. Here vol denotes the Lebesgue measure on $\Delta^{n-1}$.

We first investigate the asymptotic behaviour of the homotopy groups.
Theorem 3.4.1. Let $\nu_{n}$ be the normalized Lebesgue measure on $\Delta^{n-1}$ and let $d \geq 2$. For every $p \geq 0$, there are constants $C>0$ and $a \in(0,1)$, so that for all $n \geq 3$ the homomorphism

$$
\pi_{p}\left(E_{d}(\ell)\right) \rightarrow \pi_{p}\left(\left(S^{d-1}\right)^{n}\right) \simeq \underset{n}{\oplus} \pi_{p}\left(S^{d-1}\right)
$$

induced by inclusion is an isomorphism with probability at least $1-C a^{n}$.

Next, we study the expectations of the Betti numbers. For every $p \geq 0$, denote by $E\left(b_{p}\left(E_{d}(\ell)\right)\right)$ the mathematical expectation

$$
E\left(b_{p}\left(E_{d}(\ell)\right)\right)=\int_{\Delta^{n-1}} b_{p}\left(E_{d}(\ell)\right) d \nu_{n}
$$

of the Betti number

$$
b_{p}\left(E_{d}(\ell)\right)=\operatorname{rk} H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)
$$

of dimension $p$. It follows from the first part of Theorem 3.1.2 that

$$
E\left(b_{p}\left(E_{d}(\ell)\right)\right)=0 \text { for } p \neq 0,-1 \bmod (d-1) .
$$

Theorem 3.4.2. Let $\nu_{n}$ be the normalized Lebesgue measure on the unit simplex $\Delta^{n-1}$. Let $d>2$.

1. For every $k \geq 0$ there exist constants $C>0$ and $a \in(0,1)$, so that for all $n \geq 3$,

$$
\left|\int_{\Delta^{n-1}} b_{(d-1) k}\left(E_{d}(\ell)\right) d \nu_{n}-\binom{n}{k}\right|<C a^{n}
$$

2. For every $k \geq 1$ there exist $C>0$ and $a \in(0,1)$, so that for all $n \geq 3$,

$$
\left|\int_{\Delta^{n-1}} b_{(d-1) k-1}\left(E_{d}(\ell)\right) d \nu_{n}\right|<C a^{n} .
$$

Theorem 3.4.2 complements similar results for the expected Betti numbers of the spaces $M_{\ell}$ and $N_{\ell}$ obtained in [8]. Its proof is somewhat different: since we do not have explicit formulae for the Betti numbers of the spaces $E_{d}(\ell)$ in the case where $d$ is odd, our argument is based on the result of Proposition 1.6.8.

The claims of Theorems 3.4.1 and 3.4.2 in fact hold for a large class of probability measures on the unit simplex, as described in Definition 1 of [8]. However, for simplicity the exposition here is restricted to the case of the normalized Lebesgue measure.

Before giving the proofs of Theorems 3.4.1 and 3.4.2, we introduce some notation. Recall that a subset $J \subset\{1, \ldots, n\}$ is called short with respect to the length vector $\ell$ if

$$
\ell_{J}=\sum_{j \in J} l_{j}-\sum_{j \notin J} l_{j}<0 .
$$

For every $k \geq 0$, we consider the subset $\Gamma_{k} \subset \Delta^{n-1}$ consisting of those length vectors $\ell$, which have the property that every subset $J \subset\{1, \ldots, n\}$ of cardinality $|J|=k$ is short with respect to $\ell$. The proofs of Theorems 3.4.1 and 3.4.2 use the following estimate of the volume of the subset $\Gamma_{k}$.

Lemma 3.4.3 ([8]). For $1 \leq k \leq n$, denote by $\Gamma_{k} \subset \Delta^{n-1}$ the subset

$$
\Gamma_{k}=\left\{\ell \in \Delta^{n-1}: \ell_{J}<0 \text { for all } J \subset\{1, \ldots, n\} \text { with }|J|=k\right\} .
$$

Then

$$
1-n^{2 k} 2^{-n} \leq \frac{\operatorname{vol}\left(\Gamma_{k}\right)}{\operatorname{vol}\left(\Delta^{n-1}\right)} \leq 1
$$

The proof can be found in [8], Proposition 3 and we only recall the main idea. For every $J \subset\{1, \ldots, n\}$, consider the subset $V_{J} \subset \Delta^{n-1}$ given by $V_{J}=\left\{\ell \in \Delta^{n-1}\right.$ : $\left.\ell_{J} \geq 0\right\}$. We can express $\Gamma_{k} \subset \Delta_{n-1}$ as the union

$$
\Gamma_{k}=\Delta^{n-1}-\cup_{|J|=k} V_{J} .
$$

One observes that $V_{J} \subset \Delta^{n-1}$ is the frustum obtained by intersecting $\Delta_{n-1} \subset \mathbb{R}^{n}$ with the half-space $\left\{\ell_{J} \geq 0\right\} \subset \mathbb{R}^{n}$ and proceeds by applying known explicit formulae for the volume of a frustum of a simplex.

We are ready to give the proof of Theorem 3.4.1.

Proof of Theorem 3.4.1. If $\ell \in \Gamma_{k}, k \geq 1$, then every subset $J \subset\{1, \ldots, n\}$ which is long with respect to $\ell$ has cardinality $|J|>k$. It follows from Proposition 1.6.8 that in this case the inclusion homomorphism

$$
i_{p}: \pi_{p}\left(E_{d}(\ell)\right) \rightarrow \pi_{p}\left(\left(S^{d-1}\right)^{n}\right)
$$

is an isomorphism if $p<(d-1) k-1$. Since $d \geq 2$, the probability for $i_{p}$ to be an isomorphism can be estimated from below by

$$
\nu_{n}\left(\Gamma_{p+2}\right)=\frac{\operatorname{vol}\left(\Gamma_{p+2}\right)}{\operatorname{vol}\left(\Delta^{n-1}\right)} \geq 1-n^{2(p+2)} 2^{-n}>1-C a^{n}
$$

where $a \in(1 / 2,1)$ and where the constant $C>0$ is chosen so that $C>n^{2(p+2)}(2 a)^{-n}$ for all $n \geq 3$.

Proof of Theorem 3.4.2. Let $k \geq 0$ and let $\ell \in \Gamma_{k+1}$. By the proof of Theorem3.4.1, the inclusion homomorphism $i_{p}: \pi_{p}\left(E_{d}(\ell)\right) \rightarrow \pi_{p}\left(\left(S^{d-1}\right)^{n}\right)$ is an isomorphism if

$$
p<(d-1)(k+1)-1
$$

It follows that for $\ell \in \Gamma_{k+1}$ the non-vanishing Betti numbers $b_{p}\left(E_{d}(\ell)\right)$ with $p<$ $(d-1)(k+1)-1$ are

$$
b_{(d-1) k^{\prime}}\left(E_{d}(\ell)\right)=\binom{n}{k^{\prime}}, 0 \leq k^{\prime} \leq k
$$

Next, we combine Theorem 3.1.1 and the universal coefficient Theorem to estimate the Betti numbers in the case where $\ell \in \Delta^{n-1}-\Gamma_{k+1}$. Consider the short exact sequence

$$
0 \rightarrow H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right) \otimes \mathbf{Z}_{2} \rightarrow H_{p}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow \operatorname{Tor}\left(H_{p-1}\left(E_{d}(\ell) ; \mathbf{Z}\right), \mathbf{Z}_{2}\right) \rightarrow 0
$$

of the universal coefficient theorem for homology. Using Theorem 3.1.1, the estimates

$$
a_{k}(\ell) \leq\binom{ n-1}{k} \text { and } b_{k}(\ell) \leq\binom{ n-1}{k}
$$

and the above the exact sequence, one obtains

$$
\begin{aligned}
& b_{(d-1) k}\left(E_{d}(\ell)\right) \leq \operatorname{dim} H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& \leq 2\binom{n-1}{k}+2\binom{n-1}{k-1}=2\binom{n}{k} \leq 2 n^{k}
\end{aligned}
$$

and similarly

$$
\begin{aligned}
& b_{(d-1) k-1}\left(E_{d}(\ell)\right) \leq \operatorname{dim} H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& \quad \leq\binom{ n-1}{n-1-k}+\binom{n-1}{n-2-k} \leq n^{k+1}
\end{aligned}
$$

We can now compute

$$
\begin{gathered}
\left|\int_{\Delta^{n-1}} b_{(d-1) k}\left(E_{d}(\ell)\right) d \nu_{n}-\binom{n}{k}\right| \\
=\left|\int_{\Delta^{n-1}-\Gamma_{k+1}} b_{(d-1) k}\left(E_{d}(\ell)\right) d \nu_{n}-\left(1-\frac{\operatorname{vol}\left(\Gamma_{k+1}\right)}{\operatorname{vol}\left(\Delta^{n-1}\right)}\right)\binom{n}{k}\right| \\
\leq 2\left(1-\frac{\operatorname{vol}\left(\Gamma_{k+1}\right)}{\operatorname{vol}\left(\Delta^{n-1}\right)}\right) n^{k} \leq n^{3 k+2} 2^{-n+1}<C a^{n},
\end{gathered}
$$

where $a \in(1 / 2,1)$ and the constant $C$ is chosen so that $C>2 n^{3 k+2}(2 a)^{-n}$ for all $n \geq 3$. We have established the first claim the theorem. To prove the second claim, we compute, for $k \geq 1$,

$$
\begin{gathered}
\left|\int_{\Delta^{n-1}} b_{(d-1) k-1}\left(E_{d}(\ell)\right) d \nu_{n}\right|=\left|\int_{\Delta^{n-1}-\Gamma_{k+1}} b_{(d-1) k-1}\left(E_{d}(\ell)\right) d \nu_{n}\right| \\
\quad \leq\left(1-\frac{\operatorname{vol}\left(\Gamma_{k+1}\right)}{\operatorname{vol}\left(\Delta^{n-1}\right)}\right) n^{k+1} \leq n^{3 k+3} 2^{-n}<C a^{n}
\end{gathered}
$$

where $a \in(1 / 2,1)$ and $C$ is chosen so that $C>n^{3 k+3}(2 a)^{-n}$ for all $n \geq 3$. This completes the proof.

### 3.5 Proof of Theorem 3.1.1

It will be convenient to assume for the proof that the length vector $\ell$ is ordered (see section 1.3). Since every length vector can be obtained from an ordered length vector by a permutation of the entries and since by Proposition 1.5.3, the homeomorphism type of the space $E_{d}(\ell)$ does not change when we permute the entries of $\ell$, this assumption is not restrictive.

Recall from Section 1.1 that the space $E_{d}(\ell)$ is a subset of $W=\left(S^{d-1}\right)^{n}$. Our goal is to compute the dimensions of the kernel and of the cokernel of the homomorphism

$$
\begin{equation*}
j_{k}: H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow H_{(d-1) k}\left(W ; \mathbf{Z}_{2}\right) \tag{3.9}
\end{equation*}
$$

induced by the inclusion $W-E_{d}(\ell) \hookrightarrow W$.

Consider the robot arm distance map $f_{\ell}: W \rightarrow \mathbb{R}$,

$$
\left(u_{1}, \ldots, u_{n}\right) \mapsto-\left|\sum_{j=1}^{n} l_{j} u_{j}\right|^{2}
$$

By Lemma 1.6.1, the critical points of $f_{\ell}$ consist of the zero level set $f_{l}^{-1}(0)=E_{d}(\ell)$ and all the submanifolds

$$
P_{J}=\left\{\left(u_{1}, \ldots, u_{n}\right): u_{i}=u_{j}=-u_{k} \text { for } i, j \in J, k \notin J\right\}
$$

where $J \subset\{1, \ldots, n\}$ is long with respect to $\ell$. The Morse-Bott index of $P_{J}$ is $\operatorname{ind}_{f_{l}}\left(P_{J}\right)=(d-1)(n-|J|)$.

Fix $\varepsilon \in(0,[\ell])$ and consider the subset

$$
W^{\varepsilon}=f_{\ell}^{-1}\left(\left(-\infty,-\varepsilon^{2}\right)\right) \subset W
$$

Since $-\varepsilon^{2}$ is a regular value of $f_{\ell}, W^{\varepsilon}$ is a manifold with boundary $\partial W^{\varepsilon}=f_{\ell}^{-1}\left(-\varepsilon^{2}\right)$. The flow of $f_{\ell}$ defines a retraction of $f_{\ell}^{-1}(-\infty, 0)=W-E_{d}(\ell)$ onto $W^{\varepsilon}$.

Due to the choice of $\varepsilon$, for every subset $J \subset\{1, \ldots, n\}$ which is long with respect to $\ell$ there is an inclusion $P_{J} \subset W^{\varepsilon}$. Every submanifold $P_{J}$ is diffeomorphic to the sphere $S^{d-1}$ and its Morse-Bott index is a multiple of $(d-1)$. Thus if $d>2$, then the pair $\left(W^{\varepsilon}, f_{\ell}\right)$ satisfies the assumptions of Theorem 2.2.2. It follows that in this case the restriction of $f_{\ell}$ to the complement $W-E_{d}(\ell)$ is perfect and hence

$$
H_{*}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq H_{*}\left(W^{\varepsilon} ; \mathbf{Z}_{2}\right) \simeq \bigoplus_{J \text { long w.r.t. } \ell} H_{*-\operatorname{ind}_{f_{l}(P)}\left(P_{J} ; \mathbf{Z}_{2}\right) . . . . . .}
$$

Next, we use the criterion of Theorem 2.3.1 to identify a homology basis for $W$ $E_{d}(\ell)$.

Fix $e \in S^{d-1}$ and define for every subset $J \subset\{1, \ldots, n\}$ submanifolds $V_{J}, W_{J} \subset W$ by

$$
\begin{equation*}
V_{J}=\left\{\left(u_{1}, \ldots, u_{n}\right) \in W: u_{j}=e \text { for } j \in J\right\} \tag{3.10}
\end{equation*}
$$

and

$$
\begin{equation*}
W_{J}=\left\{\left(u_{1}, \ldots, u_{n}\right) \in W: u_{i}=u_{j} \text { for } i, j \in J\right\} . \tag{3.11}
\end{equation*}
$$

Thus $V_{J}$ is obtained by fixing the direction of all the segments of the robot arm whose indices lie in $J$ to be $e \in S^{d-1}$ while $W_{J}$ consists of all those configurations of the robot arm, where all the segments whose indices lie in $J$ are parallel.

The dimensions of $V_{J}$ and of $W_{J}$ are

$$
\operatorname{dim} V_{J}=(d-1)(n-|J|)
$$

and

$$
\operatorname{dim} W_{J}=(d-1)(n-|J|+1)
$$

For every $J \subset\{1, \ldots, n\}, V_{J} \subset W_{J}$. If the set $J$ is long with respect to $\ell$, then $W_{J} \subset W^{\varepsilon}$. Moreover in this case the class $\left[V_{J}\right] \in H_{(d-1)(n-|J|)}\left(W_{\varepsilon} ; \mathbf{Z}_{2}\right)$ is independent of the choice of the point $e \in S^{d-1}$.

We claim that the assumptions of Theorem 2.3.1 are satisfied. To this end, note that the submanifolds $P_{J}$ and $V_{J}$ of $W_{J}$ intersect transversally in a single point $e_{J} \in W$ given by

$$
u_{j}= \begin{cases}e & \text { if } j \in J \\ -e & \text { if } j \notin J\end{cases}
$$

Moreover, the inequality $f_{\ell}(q)>f_{\ell}\left(q^{\prime}\right)$ holds for all $q \in P_{J}, q^{\prime} \in W_{J}-P_{J}$. Indeed, $W_{J} \subset W$ is the subset of those configurations of the robot arm, where all segments with indices in $J$ point in the same direction. Since the function $f_{\ell}$ measures the negative distance between the initial point and the endpoint of the robot arm, the maximum of $f_{\ell}$ on $W_{J}$ is attained exactly at those configurations of the arm, where all the segments with indices not in $J$ point in the opposite direction.

Applying Theorem 2.3.1, we obtain:
Proposition 3.5.1. The classes $\left[W_{J}\right],\left[V_{K}\right]$ where $J, K \subset\{1, \ldots, n\}$ are long with respect to $\ell$ and $|J|=n-k+1,|K|=n-k$, form a basis of the $\mathbf{Z}_{2}$-vector space $H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right)$.

For $1 \leq k \leq n$, a basis of $H_{(d-1) k}\left(W ; \mathbf{Z}_{2}\right)$ is given by the classes [ $V_{K}$ ], where $K \subset$ $\{1, \ldots, n\}$ is a subset of cardinality $|K|=n-k$. For $|K|+\left|K^{\prime}\right|=n$, the mod 2 intersection number of the classes $\left[V_{K}\right]$ and $\left[V_{K^{\prime}}\right]$ is

$$
\left[V_{K}\right] \cdot\left[V_{K^{\prime}}\right]= \begin{cases}1 & \text { if } K \cap K^{\prime}=\emptyset \\ 0 & \text { if } K \cap K^{\prime} \neq \emptyset\end{cases}
$$

The intersection numbers involving the classes $\left[W_{J}\right]$ are as follows:
Lemma 3.5.2. 1. For $J, K \subset\{1, \ldots, n\},|J|+|K|=n+1$ the intersection number $\left[W_{J}\right] \cdot\left[V_{K}\right] \in \mathbf{Z}_{2}$ of the classes $\left[W_{J}\right]$ and $\left[V_{K}\right]$ is given by

$$
\left[W_{J}\right] \cdot\left[V_{K}\right]= \begin{cases}1 & \text { if }|J \cap K|=1 \\ 0 & i f|J \cap K|>1\end{cases}
$$

2. For every pair of subsets $I, J \subset\{1, \ldots, n\}$ with $|I|+|J|=n+2$ the intersection number $\left[W_{I}\right] \cdot\left[W_{J}\right] \in \mathbf{Z}_{2}$ vanishes.

Proof. Let $|J \cap K|>1$. Fix $k \in K \cap J$ and $e^{\prime} \in S^{d-1}$ with $e^{\prime} \neq e$. Consider the submanifold $V_{K}^{\prime} \subset W$ given by

$$
V_{K}^{\prime}=\left\{\left(u_{1}, \ldots, u_{n}\right) \in W: u_{j}=e \text { for } j \in K-\{k\} \text { and } u_{k}=e^{\prime}\right\}
$$

Then $\left[V_{K}\right]=\left[V_{K}^{\prime}\right]$ and $W_{J} \cap V_{K}^{\prime}=\emptyset$. We conclude that in this case $\left[W_{J}\right] \cdot\left[V_{K}\right]=0$.

If $|J \cap K|=1$ then the submanifolds $W_{J}$ and $V_{K}$ have a unique point of intersection given by $u_{j}=e$ for $j=1, \ldots, n$. This intersection is transverse.

To demonstrate the second part of the claim, let $j \in I \cap J$. Fix a diffeomorphism $\varphi: S^{d-1} \rightarrow S^{d-1}$ which is homotopic to the identity and has no fixed points (if $d$ is even) or two nondegenerate fixed points (if $d$ is odd). Define $\Phi:\left(S^{d-1}\right)^{n} \rightarrow\left(S^{d-1}\right)^{n}$ as the map which applies $\varphi$ to the $j$ th factor and fixes all other factors. Then $\left[\Phi\left(W_{I}\right)\right]=\left[W_{I}\right]$ and the submanifolds $\Phi\left(W_{I}\right)$ and $W_{J}$ are either disjoint or intersect transversally in exactly two points. Thus the mod 2 intersection number is zero.

Let us use Lemma 3.5.2 to choose a basis of $H_{*}\left(W ; \mathbf{Z}_{2}\right)$ which will be more convenient for the proof of Theorem 3.1.1.

Lemma 3.5.3. For $0 \leq k \leq n$, there is a basis of $H_{(d-1) k}\left(W ; \mathbf{Z}_{2}\right)$ consisting of the classes $\left[W_{J}\right]$ and $\left[V_{K}\right]$ where $J \subset\{1, \ldots, n\}$ is a subset with $|J|=n-k+1$ and $n \in J$ and $K \subset\{1, \ldots, n\}$ a subset with $|K|=n-k$ and $n \in K$.

Proof. Denote $H_{k}=H_{(d-1) k}\left(W ; \mathbf{Z}_{2}\right)$ and let $H_{k}^{\prime} \subset H_{k}$ be the subspace generated by the classes $\left[W_{J}\right]$ and $\left[V_{K}\right]$ as in the claim of the Lemma. Since the number $\binom{n-1}{k-1}+\binom{n-1}{k}$ of the specified generators of $H_{k}^{\prime}$ coincides with the rank $\binom{n}{k}$ of $H_{k}$, it suffices to check that the intersection form of $W$ restricts to a nondegenerate bilinear form

$$
H_{k}^{\prime} \times H_{n-k} \rightarrow \mathbf{Z}_{2}
$$

There is a basis of $H_{n-k}$ consisting of the classes $\left[V_{I}\right]$ so that $I \subset\{1, \ldots, n\}$ and $|I|=k$. We denote by $E_{n-k} \subset H_{n-k}$ (respectively by $F_{n-k} \subset H_{n-k}$ ) the subspace generated by all the classes $\left[V_{I}\right]$ so that $|I|=k$ and $n \in I$ (respectively by all the classes $\left[V_{I}\right]$ so that $|I|=k$ and $n \notin I$ ). Further, we write $E_{k}^{\prime} \subset H_{k}^{\prime}$ (respectively $\left.F_{k}^{\prime} \subset H_{k}^{\prime}\right)$ for the subspace generated by all the classes $\left[W_{J}\right]$ with $|J|=n-k+1$ and $n \in J$ (respectively by all the classes $\left[V_{K}\right]$ with $|K|=n-k$ and $n \in J$ ). Then

$$
H_{k}^{\prime}=E_{k}^{\prime} \oplus F_{k}^{\prime}
$$

and

$$
H_{n-k}=E_{n-k} \oplus F_{n-k} .
$$

Since the intersection number $\left[V_{K}\right] \cdot\left[V_{I}\right]$ is zero if both sets $K$ and $I$ contain the index $n$, the intersection form vanishes identically on $F_{k}^{\prime} \times E_{n-k}$. It follows from Lemma 3.5.2 that for $\left[W_{J}\right] \in E_{k}^{\prime}$ and $\left[V_{I}\right] \in E_{n-k}$ the intersection number $\left[W_{J}\right] \cdot\left[V_{I}\right]$ is non-zero if and only if $I=\bar{J} \cup\{n\}$. Thus the intersection form is nondegenerate on $E_{k}^{\prime} \times E_{n-k}$. One concludes analogously that the intersection form is nondegenerate on $F_{k}^{\prime} \times F_{n-k}$. This completes the proof.

Remark 3.5.4. It follows from Lemma 3.5 .2 that the duals with respect to the intersection form on $H_{*}\left(W ; \mathbf{Z}_{2}\right)$ of the basis elements of Lemma 3.5.3 are given by

$$
\left[W_{J}\right]^{*}=\left[V_{\widehat{J}}\right] \text { and }\left[V_{K}\right]^{*}=\left[W_{\widehat{K}}\right] .
$$

Here for a subset $J \subset\{1, \ldots, n\}$ with $n \in J$ the symbol $\widehat{J}$ denotes the set $\widehat{J}=$ $\bar{J} \cup\{n\}$.

We are ready to determine the dimensions of the kernel and of the cokernel of homomorphism (3.9). We write $H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ as a direct sum

$$
H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right)=A_{k} \oplus A_{k}^{\prime} \oplus B_{k} \oplus B_{k}^{\prime}
$$

where:

- $A_{k}$ (respectively $A_{k}^{\prime}$ ) is generated by classes $\left[W_{J}\right]$ with $|J|=n-k+1, J$ long with respect to $\ell$ and $n \in J$ (respectively $n \notin J$ ).
- $B_{k}$ (respectively $B_{k}^{\prime}$ ) is generated by classes $\left[V_{K}\right]$ with $|K|=n-k, K$ long with respect to $\ell$ and $n \in K$ (respectively $n \notin K$ ).

We write

$$
H_{(d-1) k}\left(W ; \mathbf{Z}_{2}\right)=A_{k} \oplus B_{k} \oplus C_{k} \oplus D_{k}
$$

where $A_{k}$ and $B_{k}$ are as above and

- $C_{k}$ is generated by the classes $\left[W_{J}\right]$ with $|J|=n-k+1, n \in J$ and $J$ either short or median with respect to $\ell$.
- $D_{k}$ is generated by the classes $\left[V_{K}\right]$ with $|K|=n-k, n \in K$ and $K$ either short or median with respect to $\ell$.

The homomorphism $j_{k}$ restricts to the identity map on $A_{k} \oplus B_{k}$.
Lemma 3.5.5. There are inclusions

$$
\begin{equation*}
j_{k}\left(A_{k}^{\prime}\right) \subset A_{k} \tag{3.12}
\end{equation*}
$$

and

$$
\begin{equation*}
j_{k}\left(B_{k}^{\prime}\right) \subset A_{k} \oplus B_{k} . \tag{3.13}
\end{equation*}
$$

Proof. Assume $\left[W_{I}\right] \in A_{k}^{\prime}$ and thus $|I|=n-k+1, I$ is long with respect to $\ell$ and $n \notin I$. Using Remark 3.5.4, one obtains the following Fourier decomposition:

$$
\begin{equation*}
j_{k}\left(\left[W_{I}\right]\right)=\sum_{\left[W_{J}\right]}\left(\left[W_{I}\right] \cdot\left[V_{\widehat{J}}\right]\right)\left[W_{J}\right]+\sum_{\left[V_{K}\right]}\left(\left[W_{I}\right] \cdot\left[W_{\widehat{K}}\right]\right)\left[V_{K}\right] . \tag{3.14}
\end{equation*}
$$

Here the first sum is over subsets $J \subset\{1, \ldots, n\}$ with $|J|=n-k+1$ and $n \in J$ and the second sum is over subsets $K \subset\{1, \ldots, n\}$ with $|K|=n-k$ and $n \in K$.

By Lemma 3.5.2, every coefficient $\left[W_{I}\right] \cdot\left[W_{\widehat{K}}\right]$ in the second sum on the right-hand side of (3.14) vanishes. Thus

$$
j_{k}\left(\left[W_{I}\right]\right) \in A_{k} \oplus C_{k} .
$$

To show that the class $j_{k}\left(\left[W_{I}\right]\right)$ lies in $A_{k}$, we must check that for every subset $J \subset\{1, \ldots, n\}$ which is either short or median with respect to $\ell$ and so that $|J|=n-k+1$ and $n \in J$, we have $\left[W_{I}\right] \cdot\left[V_{\vec{J}}\right]=0$. Recall that the intersection number $\left[W_{I}\right] \cdot\left[V_{\widehat{J}}\right]$ is non-zero if and only if the subsets $I$ and $\widehat{J}$ have exactly one element in common. The latter condition is equivalent to the set $J$ being of the form $J=I-\{i\} \cup\{n\}$ for some $i \in I$. Since $l_{n}$ is a maximal entry of $\ell$, this is a contradiction to the assumption that $I$ is long and $J$ is short or median with respect to $\ell$. We have established (3.12).

We now demonstrate (3.13). Let $\left[V_{L}\right] \in B_{k}^{\prime}$. This means that $|L|=n-k, L$ is long with respect to $\ell$ and $n \notin L$. As above, there is a decomposition

$$
\begin{equation*}
j_{k}\left(\left[V_{L}\right]\right)=\sum_{\left[W_{J}\right]}\left(\left[V_{L}\right] \cdot\left[V_{\widehat{J}}\right]\right)\left[W_{J}\right]+\sum_{\left[V_{K}\right]}\left(\left[W_{L}\right] \cdot\left[W_{\widehat{K}}\right]\right)\left[V_{K}\right], \tag{3.15}
\end{equation*}
$$

where the sums are over subsets $J$ and $K$ of $\{1, \ldots, n\}$ containing the index $n$ with $|J|=n-k+1$ and $|K|=n-k$. We must show that in the two sums on the right-hand side of (3.15) all the coefficients corresponding to basis elements [ $W_{J}$ ], [ $V_{K}$ ] which lie in $C_{k}$ respectively in $D_{k}$ vanish.

If $\left[W_{J}\right] \in C_{k}$, then $n \in J$ and $J$ is either short or median with respect to $\ell$. The intersection number $\left[V_{L}\right] \cdot\left[V_{\widehat{J}}\right]$ is non-zero if and only if $J=L \cup\{n\}$, contradicting the assumption that $L$ is long and $J$ is short or median with respect to $\ell$. Let $\left[V_{K}\right] \in D_{k}$. This means that $|K|=n-k, n \in K$ and that $K$ is short or median with respect to $\ell$. The intersection number $\left[V_{J}\right] \cdot\left[W_{\widehat{K}}\right]$ is non-zero only if $K=J-\{j\} \cup\{n\}$ for some $j \in J$. This contradicts the assumption that $J$ is long and $K$ is short or median with respect to $\ell$. This completes the proof of (3.13).

Corollary 3.5.6. The image of the homomorphism $j_{k}$ is generated by all the classes $\left[W_{J}\right]$ and $\left[V_{K}\right]$ so that the subsets $J, K \subset\{1, \ldots, n\}$ are long with respect to $\ell$, contain the index $n$ and have the cardinalities $|J|=n-k+1$ and $|K|=n-k$.

Thus

$$
\begin{gathered}
\operatorname{dim}_{\mathbf{Z}_{2}} \operatorname{coker}\left(j_{k}\right)=\operatorname{dim}_{\mathbf{Z}_{2}} C_{k}+\operatorname{dim}_{\mathbf{Z}_{2}} D_{k} \\
=a_{n-k}(\ell)+b_{n-k}(\ell)+a_{n-k-1}(\ell)+b_{n-k-1}(\ell) .
\end{gathered}
$$

On the other hand, from Proposition 3.5.5

$$
\operatorname{dim}_{\mathbf{Z}_{2}} \operatorname{ker}\left(j_{k}\right)=\operatorname{dim}_{\mathbf{Z}_{2}} A_{k}^{\prime}+\operatorname{dim}_{\mathbf{Z}_{2}} B_{k}^{\prime}=a_{k-2}(\ell)+a_{k-1}(\ell) .
$$

Consider the exact sequence of the pair $\left(W, W-E_{d}(\ell)\right)$ for homology with $\mathbf{Z}_{2}{ }^{-}$ coefficients. Using the fact that the non-vanishing homology groups $H_{*}\left(W ; \mathbf{Z}_{2}\right)$ and $H_{*}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ are concentrated in dimensions which are multiples of $d-1$, we see that non-vanishing homology groups $H_{p}\left(W, W-E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ are concentrated in dimensions of the form $p=(d-1) k$ and $p=(d-1) k+1, k \geq 0$. Moreover, if $d>2$, then there is an exact sequence

$$
\begin{aligned}
0 \rightarrow & H_{(d-1) k+1}\left(W, W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& \xrightarrow{j_{k}} H_{(d-1) k}\left(W ; \mathbf{Z}_{2}\right) \rightarrow H_{(d-1) k}\left(W, W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow 0 .
\end{aligned}
$$

Using Poincaré-Lefschetz duality and excision,

$$
H_{*}\left(W, W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq H^{(d-1) n-*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

Thus

$$
\begin{aligned}
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) & =\operatorname{dim}_{\mathbf{Z}_{2}} H^{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& =\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1)(n-k)}\left(W, W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& =\operatorname{dim}_{\mathbf{Z}_{2}} \operatorname{coker}\left(j_{n-k}\right) \\
& =a_{k}(\ell)+b_{k}(\ell)+a_{k-1}(\ell)+b_{k-1}(\ell)
\end{aligned}
$$

and

$$
\begin{aligned}
\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) & =\operatorname{dim}_{\mathbf{Z}_{2}} H^{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& =\operatorname{dim}_{\mathbf{Z}_{2}} H_{(d-1)(n-k)+1}\left(W, W-E_{d}(\ell) ; \mathbf{Z}_{2}\right) \\
& =\operatorname{dim}_{\mathbf{Z}_{2}} \operatorname{ker}\left(j_{n-k}\right) \\
& =a_{n-k-2}(\ell)+a_{n-k-1}(\ell) .
\end{aligned}
$$

The proof of Theorem 3.1.1 is complete.

### 3.6 Proof of Theorems 3.1.2, 3.1.3 and 3.1.5

Proof of Theorem 3.1.2. In course of the proof of Theorem 3.1.1 in the previous section, homology classes in $H_{*}\left(W ; \mathbf{Z}_{2}\right)$ defined by submanifolds $V_{K}, W_{J} \subset W$ were used. In order to obtain integral homology classes, we now orient the submanifolds $V_{K}, W_{J}$.

We orient each submanifold $V_{K} \subset W$ as the product $V_{K}=\left(S^{d-1}\right)^{n-|K|} \subset\left(S^{d-1}\right)^{n}=$ $W$. In more detail, let $\left\{i_{1}<\cdots<i_{k}\right\}$ be the complement of $K$ in $\{1, \ldots, n\}$. For every element $u=\left(u_{1}, \ldots, u_{n}\right) \in V_{K}$, let $B_{i_{1}}, \ldots, B_{i_{k}}$ be bases of the tangent spaces $T_{u_{i_{1}}} S^{d-1}, \ldots, T_{u_{i_{k}}} S^{d-1}$ which are positive with respect to the standard orientation of the sphere. We fix an orientation of the tangent space $T_{u} V_{K}$ by defining the basis $\left(B_{i_{1}}, \ldots, B_{i_{k}}\right)$ to be positive.

Every submanifold $W_{J} \subset W$ is oriented as the product of the corresponding manifold $V_{J}$ and the diagonal in $\left(S^{d-1}\right)^{n-|J|}$. More precisely, let $u=\left(u_{1}, \ldots, u_{n}\right) \in W_{J}$. By definition of $W_{J}$, this means that $u_{j}=e$ for all $j \in J$. We identify $T_{u} W_{J} \simeq$ $T_{u} V_{J} \oplus T_{e} S^{d-1}$ and orient $T_{u} W_{J}$ by declaring a basis of $T_{u} W_{J}$ consisting of a positive basis of $T_{u} V_{J}$, followed by a positive basis of $T_{e} S^{d-1}$, to be positive.

We now apply Corollary 2.3 .2 to conclude:
Proposition 3.6.1. The homology classes $\left[W_{J}\right],\left[V_{K}\right]$ with $|J|=n-k+1,|K|=$
$n-k$ and so that the sets $J$ and $K$ are long with respect to $\ell$, form a free basis of $H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)$.

Consider the exact sequence of the pair $\left(W, W-E_{d}(\ell)\right)$ for homology with integral coefficients. The non-vanishing homology groups $H_{*}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)$ are concentrated in dimensions which are multiples of $d-1$. Using excision and Poincaré duality, there is an isomorphism

$$
H_{*}\left(W, W-E_{d}(\ell) ; \mathbf{Z}\right) \simeq H^{(d-1) n-*}\left(E_{d}(\ell) ; \mathbf{Z}\right)
$$

We see from the exact sequence that the non-vanishing groups $H^{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ lie in dimensions

$$
p=(d-1) k, 0 \leq k \leq n-2 \text { and } p=(d-1) k-1,1 \leq k \leq n-1 .
$$

Moreover, cohomology groups of the form $H^{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ are torsion-free. The two assertions of the theorem now follow from the universal coefficient theorem for cohomology.

We will conclude Theorems 3.1.3 and 3.1.5 from the following result:

Lemma 3.6.2. Let

$$
j_{k}: H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right) \rightarrow H_{(d-1) k}(W ; \mathbf{Z})
$$

be the homomorphism induced by the inclusion $W-E_{d_{\ell}} \hookrightarrow W$.

1. If $d$ is even, then the cokernel of the homomorphism $j_{k}$ is torsion-free.
2. Let $d$ be odd. The following conditions are equivalent:
(a) The cokernel of $j_{k}$ contains torsion elements;
(b) There exists a subset $J \subset\{1, \ldots, n-1\}$ of cardinality $|J|=n-k+1$ which is long with respect to $\ell$ and indices $i, j \in J$, so that the set $I=$ $J-\{i, j\} \cup\{n\}$ is short or median with respect to $\ell$.

We now show that Theorems 3.1.3 and 3.1.5 follow from Lemma 3.6.2,

Proof of Theorems 3.1.3 and 3.1.5. As in the proof of Theorem 3.1.1, it follows from the exact homology sequence of the pair $\left(W, W-E_{d}(\ell)\right)$ that there is an isomorphism

$$
H^{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}\right) \simeq \operatorname{coker}\left(j_{n-k}\right)
$$

If $T_{(d-1) k-1} \subset H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ denotes the subgroup consisting of torsion elements, then by the universal coefficient theorem for cohomology,

$$
H^{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}\right) \simeq H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}\right) \oplus T_{(d-1) k-1}
$$

Here we used the fact that the homology group $H_{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ is free abelian by Theorem 3.1.2.

We see that the homology group $H_{(d-1) k-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ contains torsion elements if and only if the cokernel of the homomorphism $j_{n-k}$ contains torsion elements. The claims of Theorems 3.1 .3 and 3.1 .5 now follow from the first respectively the second part of Lemma 3.6.2.

Recall that by Proposition 3.6.1, the group $H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)$ has a free basis consisting of all the classes $\left[V_{K}\right],\left[W_{J}\right]$ so that $K$ and $J$ are long subsets with $|K|=$ $n-k$ and $|J|=n-k+1$. We write $H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)$ as a direct sum

$$
\begin{equation*}
H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)=E_{k} \oplus E_{k}^{\prime} \oplus B_{k} \oplus B_{k}^{\prime} \tag{3.16}
\end{equation*}
$$

of free abelian groups. Here $B_{k}$ and $B_{k}^{\prime}$ are defined as in the proof of Proposition 3.1.1 in the previous section: $B_{k} \subset H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)$ (respectively $\left.B_{k}^{\prime} \subset H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)\right)$ is the subgroup generated by all the classes $\left[V_{K}\right]$ so that $|K|=n-k, K$ is long with respect to $\ell$ and $n \in K$ (respectively all the classes $\left[V_{K}\right]$ so that $|K|=n-k, K$ is long with respect to $\ell$ and $\left.n \notin K\right)$.

Moreover, $E_{k}$ and $E_{k}^{\prime}$ are defined as follows:

- $E_{k}$ is the subgroup generated by all the classes $\left[W_{J}\right]$ so that $|J|=n-k+1$, $n \in J, J$ is long with respect to $\ell$ and so that the set $J-\{n\}$ is either short or median with respect to $\ell$.
- $E_{k}^{\prime}$ is the subgroup generated by all the remaining basis elements $\left[W_{J}\right]$ : the generators of $E_{k}^{\prime}$ are all the classes $\left[W_{J}\right] \in E_{k}^{\prime}$ so that $|J|=n-k+1$ and one of the following two conditions is satisfied:

1. $J$ does not contain the index $n$ and is long with respect to $\ell$;
2. $J$ contains $n$ and the set $J-\{n\}$ is long with respect to $\ell$.

There is a free basis of $H_{(d-1) k}(W ; \mathbf{Z})$ consisting of the classes [ $V_{K}$ ], where $K \subset$ $\{1, \ldots, n\}$ is a subset of cardinality $|K|=n-k$. We write $H_{(d-1) k}(W ; \mathbf{Z})$ as a direct sum

$$
\begin{equation*}
H_{(d-1) k}(W ; \mathbf{Z})=F_{k} \oplus F_{k}^{\prime} \oplus B_{k} \oplus B_{k}^{\prime} \tag{3.17}
\end{equation*}
$$

of free abelian groups, where the groups $B_{k}$ and $B_{k}^{\prime}$ are defined as above and the groups $F_{k}$ and $F_{k}^{\prime}$ are defined as follows:

- $F_{k}$ is generated by all the classes $\left[V_{K}\right]$ with $|K|=n-k, n \notin K$ and so that the set $K$ is short or median with respect to $\ell$ and the set $K \cup\{n\}$ is long.
- $F_{k}^{\prime}$ is generated by all the remaining basis elements $\left[V_{K}\right]$. Namely, generators of $F_{k}^{\prime}$ are all the classes $\left[V_{K}\right]$ so that $|K|=n-k$ and so that one of the following two conditions is satisfied:

1. $K$ contains the index $n$ and is short or median with respect to $\ell$;
2. $K$ does not contain $n$ and the set $K \cup\{n\}$ is short or median with respect to $\ell$.

The homomorphism $j_{k}: H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right) \rightarrow H_{(d-1) k}(W ; \mathbf{Z})$ is the identity on $B_{k} \oplus B_{k}^{\prime}$. It follows that the cokernel of $j_{k}$ is isomorphic to the cokernel of the composition of $j_{k}$ with the projection

$$
\begin{aligned}
\pi: F_{k} \oplus F_{k}^{\prime} \oplus B_{k} \oplus B_{k}^{\prime} & \rightarrow\left(F_{k} \oplus F_{k}^{\prime} \oplus B_{k} \oplus B_{k}^{\prime}\right) /\left(B_{k} \oplus B_{k}^{\prime}\right) \\
& =F_{k} \oplus F_{k}^{\prime} .
\end{aligned}
$$

Denote by

$$
j_{k}^{\prime}: H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right) \rightarrow F_{k} \oplus F_{k}^{\prime}
$$

the composition $\pi \circ j_{k}$. Next, we describe the homomorphism $j_{k}^{\prime}$.

By construction, $j_{k}^{\prime}$ vanishes identically on the subgroup

$$
B_{k} \oplus B_{k}^{\prime} \subset H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right) .
$$

Consider an element $\left[W_{J}\right]$ of the specified basis of $E_{k} \subset H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)$. We compute

$$
\begin{equation*}
j_{k}^{\prime}\left(\left[W_{J}\right]\right)=\sum_{\left[V_{K}\right] \in F_{k}} \frac{\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]}{\left[V_{K}\right] \cdot\left[V_{\bar{K}}\right]}\left[V_{K}\right]+\sum_{\left[V_{I}\right] \in F_{k}^{\prime}} \frac{\left[W_{J}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}\left[V_{I}\right], \tag{3.18}
\end{equation*}
$$

where the first sum is over all basis elements $\left[V_{K}\right]$ of $F_{k}$ and the second sum over all basis elements $\left[V_{I}\right]$ of $F_{k}^{\prime}$. By definition of the subgroup $E_{k}, J$ is a long subset with $n \in J$ so that the set $J-\{n\}$ is either short or median with respect to $\ell$. On the other hand, the set $K$ does not contain the index $n$. Moreover, $K$ is short or median with respect to $\ell$ and the set $K \cup\{n\}$ is long with respect to $\ell$.

It follows from the proof of Proposition 3.5 .2 that the intersection number $\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]$ is non-zero if and only if the sets $J$ and $\bar{K}$ have exactly one element in common; moreover in this case we have $\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]= \pm 1$ (the exact sign can be determined from the above choice of orientations of the submanifolds $W_{J}, V_{K}$, but this will not be used). Since $n \in J$ and $n \in \bar{K}$, the coefficient of $\left[V_{K}\right]$ in the first sum on the right-hand side of (3.18) is non-zero if and only if $K=J-\{n\}$; moreover in this case the coefficient equals $\pm 1$.

We define for every basis element $\left[V_{K}\right.$ ] of $F_{k}$

$$
\begin{equation*}
Y_{K}=\frac{\left[W_{K^{\prime}}\right] \cdot\left[V_{\bar{K}}\right]}{\left[V_{K}\right] \cdot\left[V_{\bar{K}}\right]}\left[V_{K}\right]+\sum_{\left[V_{I}\right] \in F_{k}^{\prime}} \frac{\left[W_{K^{\prime}}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}\left[V_{I}\right], \tag{3.19}
\end{equation*}
$$

where $K^{\prime}$ denotes the set $K^{\prime}=K \cup\{n\}$.

Let $\widetilde{F}_{k} \subset F_{k} \oplus F_{k}^{\prime}$ be the free abelian group generated by the classes $Y_{K}$. We have $F_{k} \oplus F_{k}^{\prime}=\widetilde{F}_{k} \oplus F_{k}^{\prime}$. From the definition of $Y_{K}$ and the above discussion of equation (3.18) we see that $j_{k}^{\prime}\left(\left[W_{K}\right]\right)=Y_{K}$ for $\left[W_{K}\right] \in E_{k}$. Thus

$$
j_{k}^{\prime}\left(E_{k}\right)=\widetilde{F}_{k}
$$

and moreover $j_{k}^{\prime}$ restricts to an isomorphism of $E_{k}$ onto $\widetilde{F}_{k}$. It follows that if

$$
j_{k}^{\prime \prime}: H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right) \rightarrow F_{k}^{\prime}
$$

denotes the composition $\pi^{\prime} \circ j_{k}^{\prime}$ of $j_{k}^{\prime}$ and the projection

$$
\pi^{\prime}: \widetilde{F}_{k} \oplus F_{k}^{\prime} \rightarrow\left(\widetilde{F}_{k} \oplus F_{k}^{\prime}\right) / \widetilde{F}_{k}=F_{k}^{\prime}
$$

then the cokernel of $j_{k}^{\prime}$ is isomorphic to the cokernel of $j_{k}^{\prime \prime}$.

We now describe the homomorphism $j_{k}^{\prime \prime}$. By construction, $j_{k}^{\prime \prime}$ vanishes identically on the subgroup

$$
E_{k} \oplus B_{k} \oplus B_{k}^{\prime} \subset H_{(d-1) k}\left(W-E_{d}(\ell) ; \mathbf{Z}\right)
$$

Next, let $\left[W_{J}\right]$ be an element of the specified basis of $E_{k}^{\prime}$. Consider the right-hand side of (3.18). The intersection number $\left[W_{J}\right] \cdot\left[V_{\bar{I}}\right]$ is non-zero if and only if the sets $J$ and $\bar{I}$ have exactly one element in common or, equivalently, if $J$ is obtained from $I$ by adding a single element of the complement $\bar{I}$. Examining the definitions of the subgroups $E_{k}^{\prime}$ and $F_{k}^{\prime}$, we find that this is impossible. Indeed, assume that $n \in I$ and $J=I \cup\{j\}$ for some $j \in \bar{I}$. Since $n \in J$, it follows from the definition of $E_{k}^{\prime}$ that the set $J-\{n\}=I \cup\{j\}-\{n\}$ is long with respect to $\ell$. However, since $l_{n}$ is a maximal entry of $\ell$, in this case the set $I$ must be long as well in contradiction to the definition of $F_{k}^{\prime}$. For $n \notin I$ we argue similarly: since in this case by the definition of the subgroup $F_{k}^{\prime}$ the set $I \cup\{n\}$ is short or median with respect to $\ell$, so is any set of the form $I \cup\{j\}, j \in \bar{I}$.

It follows that for every basis element $\left[W_{J}\right] \in E_{k}^{\prime}$, the second sum on the righthand side of (3.18) vanishes. Thus

$$
\begin{gathered}
j_{k}^{\prime}\left(\left[W_{J}\right]\right)=\sum_{\left[V_{K}\right] \in F_{k}} \frac{\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]}{\left[V_{K}\right] \cdot\left[V_{\bar{K}}\right]}\left[V_{K}\right] \\
=\sum_{\left[V_{K}\right] \in F_{k}} \frac{\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]}{\left[W_{K^{\prime}}\right] \cdot\left[V_{\bar{K}}\right]}\left(Y_{K}-\sum_{\left[V_{I}\right] \in F_{k}^{\prime}} \frac{\left[W_{K^{\prime}}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}\left[V_{I}\right]\right) .
\end{gathered}
$$

Here $Y_{K}$ is the homology class defined in (3.19).

One concludes that

$$
\begin{equation*}
j_{k}^{\prime \prime}\left(\left[W_{J}\right]\right)=-\sum_{\left[V_{K}\right],\left[V_{I}\right]} \frac{\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]}{\left[W_{K^{\prime}}\right] \cdot\left[V_{\bar{K}}\right]} \frac{\left[W_{K^{\prime}}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}\left[V_{I}\right], \tag{3.20}
\end{equation*}
$$

where the sum is over all the elements $\left[V_{K}\right] \in F_{k}$ and $\left[V_{I}\right] \in F_{k}^{\prime}$ of the specified bases of $F_{k}$ and $F_{k}^{\prime}$.

We will use (3.20) to analyze the cokernel of the homomorphism $j_{k}^{\prime \prime}$. The result of our analysis is summarised by the following Lemma:

Lemma 3.6.3. Let $d>2$.

1. Every element of the image of the homomorphism $j_{k}^{\prime \prime}$ is divisible by two.
2. If $d$ is even, then the homomorphism $j_{k}^{\prime \prime}$ vanishes identically.
3. If $d$ is odd, then the following conditions are equivalent:
(a) $j_{k}^{\prime \prime}$ is not the zero homomorphism;
(b) There exists a subset $J \subset\{1, \ldots, n-1\}$ as in condition (b) in the second part of Lemma 3.6.2.

Let us show that Lemma 3.6 .2 follows from Lemma 3.6.3.

Proof of Lemma 3.6.2. By construction of the homomorphism $j_{k}^{\prime \prime}$, the cokernels of $j_{k}$ and of $j_{k}^{\prime \prime}$ are isomorphic. Thus the first claim of Lemma 3.6.2 follows from the second assertion of Lemma 3.6.3.

We now demonstrate that if the homomorphism $j_{k}^{\prime \prime}$ does not vanish identically, then its cokernel contains torsion elements. Using the criterion of the third part of Lemma 3.6.3, this will imply the second assertion of Lemma 3.6.2,

Assume that $j_{k}^{\prime \prime}\left(\left[W_{J}\right]\right) \neq 0$ for some basis element $\left[W_{J}\right] \in E_{k}^{\prime}$. By the first part of Lemma 3.6.3, the element $j_{k}^{\prime \prime}\left(\left[W_{J}\right]\right) \in F_{k}^{\prime}$ is divisible by two. Let $s>0$ be the maximal exponent so that $2^{s}$ divides $j_{k}^{\prime \prime}\left(\left[W_{J}\right]\right)$ and let

$$
j_{k}^{\prime \prime}\left(\left[W_{J}\right]\right)=2^{s} X, X \in F_{k}^{\prime} .
$$

Then $2^{s} X \in \operatorname{Im} j_{k}^{\prime \prime}$ but $X \notin \operatorname{Im} j_{k}^{\prime \prime}$. Thus the equivalence class of $X$ in the cokernel of $j_{k}^{\prime \prime}$ has finite order. This completes the proof.

It remains to prove Lemma 3.6.3.

Proof of Lemma 3.6.3. Consider the coefficient of $\left[V_{I}\right] \in F_{k}^{\prime}$ on the right-hand side of (3.20). The intersection number $\left[W_{J}\right] \cdot\left[V_{\bar{K}}\right]$ is non-zero if and only if the set $K$ is obtained from $J$ by removing a single element $j \in J$. Moreover, in this case we have $n \notin J$ : otherwise we would conclude from the definition of $E_{k}^{\prime}$ that the set $J-\{n\}$ is long with respect to $\ell$ and then so would be the set $K=J-\{j\}$, contradicting the condition $\left[V_{I}\right] \in F_{k}$. Similarly, the intersection number $\left[W_{K^{\prime}}\right] \cdot\left[V_{I}\right]$ is non-zero if and only if $I$ is obtained from $K^{\prime}$ by removing an element $i \in K^{\prime}$. We note that $i \neq n$, since otherwise we would have $K=I$ contradicting the fact that $F_{k}$ and $F_{k}^{\prime}$ are disjoint.

We see that a necessary condition for the coefficient of $\left[V_{I}\right]$ on the right-hand side of (3.20) to be non-zero is that the set the set $I$ may be written as $I=J-\{i, j\} \cup\{n\}$ for some pair of indices $i, j \in J, i \neq j$. In this case the coefficient is given by

$$
-\mu_{i}-\mu_{j}
$$

where

$$
\mu_{i}=\frac{\left[W_{J}\right] \cdot\left[V_{\bar{I}_{i}}\right]}{\left[W_{I_{i}}\right] \cdot\left[V_{\bar{I}_{i}}\right]} \frac{\left[W_{I_{i}^{\prime}}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}
$$

and $I_{i}=I-\{n\} \cup\{i\}$; the number $\mu_{j}$ is defined analogously, but with the index $i$ replaced by $j$. Since $\mu_{i}, \mu_{j} \in\{ \pm 1\}$, every coefficient in the sum on the right-hand side of 3.20 is even. This establishes the first claim of Lemma 3.6.3.

We will show that

$$
\begin{equation*}
\mu_{i}=-\mu_{j} \text { if } d \text { is even } \tag{3.21}
\end{equation*}
$$

and

$$
\begin{equation*}
\mu_{i}=\mu_{j} \text { if } d \text { is odd. } \tag{3.22}
\end{equation*}
$$

This will complete the proof of Lemma 3.6.3. Indeed, from (3.21) we see that in the case where $d$ is even, $j_{k}^{\prime \prime}$ vanishes identically. This establishes the second assertion
of Lemma 3.6.3.

Equation (3.22) together with the definition of the coefficients $\mu_{i}$ and $\mu_{j}$ shows that if $d$ is odd, then the homomorphism $j_{k}^{\prime \prime}$ is not identically zero if and only if there exist basis elements $\left[W_{J}\right] \in E_{k}^{\prime}$ and $\left[V_{I}\right] \in F_{k}^{\prime}$ so that $n \notin J$ and $I=J-\{i, j\} \cup\{n\}$ for some pair of indices $i, j \in J, i \neq j$. Examining the definition of the subgroups $E_{k}^{\prime}$ and $F_{k}^{\prime}$, one finds that this last condition is equivalent to condition (b) in the second part of Lemma 3.6.2.

Our proof of (3.21) and (3.22) relies on a symmetry argument. Consider the homeomorphism $\phi: W \rightarrow W$ which interchanges the $i$ th and the $j$ th factor of the product $W=\left(S^{d-1}\right)^{n}$. Since the set $J$ contains both indices $i$ and $j$ and neither of these two indices lies in $I$,

$$
\begin{equation*}
\phi\left(W_{J}\right)=W_{J}, \phi\left(V_{I}\right)=V_{I} \text { and } \phi\left(V_{\bar{I}}\right)=V_{\bar{I}} . \tag{3.23}
\end{equation*}
$$

Similarly,

$$
\begin{equation*}
\phi\left(V_{I_{i}^{\prime}}\right)=V_{I_{j}^{\prime}}, \phi\left(V_{I_{j}^{\prime}}\right)=V_{I_{i}^{\prime}} \tag{3.24}
\end{equation*}
$$

and

$$
\begin{equation*}
\phi\left(V_{\bar{I}_{i}}\right)=V_{\bar{I}_{j}}, \phi\left(V_{\bar{I}_{j}}\right)=V_{\bar{I}_{i}} . \tag{3.25}
\end{equation*}
$$

We also note that

$$
\begin{equation*}
\phi_{*}\left(\left[W_{J}\right]\right)=\left[W_{J}\right] . \tag{3.26}
\end{equation*}
$$

Assume that $d$ is even. In this case $\phi$ reverses the orientation of $W$ and thus for any two classes $x \in H_{(d-1) k}(W ; \mathbf{Z})$ and $y \in H_{(d-1)(n-k)}(W ; \mathbf{Z})$,

$$
\begin{equation*}
\phi_{*}(x) \cdot \phi_{*}(y)=-x \cdot y . \tag{3.27}
\end{equation*}
$$

Moreover, using our choice of the orientations of the submanifolds $V_{I}$,

$$
\begin{equation*}
\phi_{*}\left(\left[V_{I}\right]\right)=-\left[V_{I}\right] . \tag{3.28}
\end{equation*}
$$

We compute

$$
\begin{equation*}
\mu_{i}=\frac{\phi_{*}\left(\left[W_{J}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}_{i}}\right]\right)}{\phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}_{i}}\right]\right)} \frac{\phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}}\right]\right)}{\phi_{*}\left(\left[V_{I}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}}\right]\right)} \tag{3.29}
\end{equation*}
$$

$$
\begin{equation*}
=-\frac{\left[W_{J}\right] \cdot\left[V_{\bar{I}_{j}}\right]}{\left[W_{I_{j}^{\prime}}\right] \cdot\left[V_{\bar{I}_{j}}\right]} \frac{\left[W_{I_{j}^{\prime}}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}=-\mu_{j} . \tag{3.30}
\end{equation*}
$$

Here (3.29) follows from (3.27) and (3.30) from (3.23)-(3.26) and (3.28). Note that equations (3.23)-(3.25) imply that

$$
\begin{equation*}
\phi_{*}\left(\left[V_{\bar{I}}\right]\right)= \pm\left[V_{\bar{I}}\right], \phi_{*}\left(\left[V_{\bar{I}_{i}}\right]\right)= \pm\left[V_{\bar{I}_{j}}\right] \text { and } \phi_{*}\left(\left[V_{I_{i}^{\prime}}\right]\right)= \pm\left[V_{I_{j}^{\prime}}\right] . \tag{3.31}
\end{equation*}
$$

Each of the classes $\phi_{*}\left(\left[V_{\bar{I}}\right]\right), \phi_{*}\left(\left[V_{\bar{I}_{i}}\right)\right.$ and $\phi_{*}\left(\left[V_{\left.I_{i}^{\prime}\right]}\right)\right.$ enters the expression on the righthand side of (3.29) twice. Thus the signs carried over from the right-hand sides in (3.31) cancel.

Suppose now that $d$ is odd. In this case $\phi$ preserves the orientation of $W$ and thus for $x \in H_{(d-1) k}(W ; \mathbf{Z})$ and $y \in H_{(d-1)(n-k)}(W ; \mathbf{Z})$,

$$
\begin{equation*}
\phi_{*}(x) \cdot \phi_{*}(y)=x \cdot y \tag{3.32}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
\phi_{*}\left(\left[V_{I}\right]\right)=\left[V_{I}\right] . \tag{3.33}
\end{equation*}
$$

Arguing as in the above proof of (3.21), one obtains

$$
\begin{gathered}
\mu_{i}=\frac{\phi_{*}\left(\left[W_{J}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}_{i}}\right]\right) \frac{\phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}}\right]\right)}{\phi_{*}\left(\left[\left[W_{I_{i}^{\prime}}\right)\right) \cdot \phi_{*}\left(\left[V_{\bar{I}_{i}}\right]\right)\right.}}{\phi_{*}\left(\left[V_{I}\right]\right) \cdot \phi_{*}\left(\left[V_{\bar{I}}\right]\right)} \\
=\frac{\left[W_{J}\right] \cdot\left[V_{\bar{I}_{j}}\right]}{\left[W_{I_{j}^{\prime}}\right] \cdot\left[V_{\bar{I}_{j}}\right]} \frac{\left[V_{I}\right] \cdot\left[V_{\bar{I}}\right]}{\left[V_{\bar{I}}\right]}=\mu_{j} .
\end{gathered}
$$

This completes the proof.

## Chapter 4

## Homology of planar telescopic

## Polygons

In this chapter we compute the homology groups of spaces of polygons with a telescopic edge in the planar case $d=2$. We discuss an application motivated by the Topological Hypothesis studied in the theory of phase transitions.

### 4.1 The Homology Groups

The purpose of this section is to present a computation of the homology groups of spaces of planar polygonal linkages with a segment of variable length. Let us recall the construction of these spaces from Section 1.1. We fix length vectors $\ell^{-}$and $\ell^{+}$ of the form

$$
\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{-}\right)
$$

and

$$
\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}^{+}\right),
$$

where $l_{n}^{-}<l_{n}^{+}$, and consider the closed interval $A \subset \mathbb{R}^{n}$ connecting $\ell^{-}$and $\ell^{+}$. The space $E_{d}(A)$ of polygons in Euclidean space $\mathbb{R}^{d}$ with $n-1$ edges of fixed lengths $l_{1}, \ldots, l_{n-1}$ and an edge whose length varies in the interval $\left[l_{n}^{-}, l_{n}^{+}\right]$is defined as the union

$$
E_{d}(A)=\cup_{\ell \in A} E_{d}(\ell) \subset\left(S^{d-1}\right)^{n} .
$$

Using the second part of Proposition 1.5.5, we can assume without loss of generality that the metric data $A$ satisfies the condition $l_{1} \leq l_{2} \leq \cdots \leq l_{n-1}$.

Our study of the spaces $E_{d}(A)$ is motivated by the fact that they may be viewed as configuration spaces of linkages equipped with a telescopic segment. Telescopic legs are used quite commonly in mechanical linkages for example for shock absorption. As we show in Section 4.3, the spaces $E_{d}(A)$ are also of interest for certain topological questions studied in the thermodynamics literature.

Let us consider the space $E_{d}(A)$ in the case $d=2$. There is a free $S O(2)$-action on $E_{2}(A)$ and the same argument as used in the proof of the first part of Proposition 1.5.2 shows:

Proposition 4.1.1. If $M_{A}$ denotes the quotient space $M_{A}=E_{2}(A) / S O(2)$, then there is a homeomorphism

$$
E_{2}(A) \simeq S^{1} \times M_{A} .
$$

It will be more convenient for us to study the spaces $M_{A}$ rather than the products $E_{2}(A) \simeq S^{1} \times M_{A}$.

The main result of this chapter is the computation of the homology groups of the spaces $M_{A}$.

Theorem 4.1.2. Let $A$ be the metric data of a polygon telescopic linkage with $n-1$ segments of fixed lengths $l_{1} \leq l_{2} \leq \cdots \leq l_{n-1}$ and one telescopic segment whose length varies in the interval $\left[l_{n}^{-}, l_{n}^{+}\right], 0<l_{n}^{-}<l_{n}^{+}$. Assume that $A$ is generic (see Section 1.5). Then for every $k=0, \ldots, n-2$ the homology group $H_{k}\left(M_{A} ; \mathbf{Z}\right)$ is free abelian with rank

$$
\alpha_{k}\left(\ell^{-}\right)-\beta_{k}\left(\ell^{+}, \ell^{-}\right)+\alpha_{n-3-k}\left(\ell^{+}\right)-\beta_{n-3-k}\left(\ell^{-}, \ell^{+}\right)
$$

We refer to Section 1.4 for the definition of the numbers $\alpha_{k}$ and $\beta_{k}$.

In the next two sections, applications of Theorem 4.1.2 are discussed.

### 4.2 Examples and Applications

In this section we evaluate Theorem 4.1.2 to study the topology of the spaces $M_{A}$.

We assume throughout this section that the metric data $A$ is generic and satisfies the condition

$$
l_{1} \leq l_{2} \leq \cdots \leq l_{n-1} .
$$

Example 4.2.1. Consider the case where the interval of variation of the length of the telescopic segment is small. Namely, let $\ell=\left(l_{1}, \ldots, l_{n}\right)$ be a generic length vector and assume that

$$
\ell^{-}=\left(l_{1}, \ldots, l_{n-1}, l_{n}-\varepsilon\right)
$$

and

$$
\ell^{+}=\left(l_{1}, \ldots, l_{n-1}, l_{n}+\varepsilon\right),
$$

where $0<\varepsilon<\min \left(l_{n},[\ell]\right)$. Theorem 4.1.2 and the third part of Proposition 1.4.4 imply that for $0 \leq k \leq n-2$ the homology group $H_{k}\left(M_{A} ; \mathbf{Z}\right)$ is free abelian of rank

$$
\operatorname{rk} H_{k}\left(M_{A} ; \mathbf{Z}\right)=a_{k}(\ell)+a_{n-3-k}(\ell) .
$$

On the other hand, it follows from Proposition 1.5 .6 that in this case there is homeomorphism

$$
M_{A} \simeq M_{\ell} \times[-\varepsilon, \varepsilon] .
$$

We see that for generic length vectors Theorem 4.1.2 recovers the computation of the integral homology groups of the spaces $M_{\ell}$ of planar polygons with fixed edge lengths obtained in [15.

Example 4.2.2. Let us assume the inequalities (a) $l_{n-1}>l_{1}+\cdots+l_{n-2}$, (b) $0<l_{n}^{-}<$ $l_{n-1}-\left(l_{1}+\cdots+l_{n-2}\right)$ and (c) $l_{n}^{+}>l_{1}+\cdots+l_{n-1}$.

Recall from the proof of Proposition 1.5 .5 in Section 1.6 that the space $E_{2}(A)$ may be identified as

$$
E_{2}(A)=f_{\ell^{\prime}}^{-1}([a, b]),
$$

where $\ell^{\prime}$ denotes the length vector $\ell^{\prime}=\left(l_{1}, \ldots, l_{n-1}\right), f_{\ell^{\prime}}:\left(S^{1}\right)^{n-1} \rightarrow \mathbb{R}$ is the corresponding robot arm distance map and $a=-\left(l_{n}^{+}\right)^{2}, b=-\left(l_{n}^{-}\right)^{2}$. The minimum of
the function $f_{\ell^{\prime}}$ is given by $-\left(l_{1}+\cdots+l_{n-1}\right)^{2}$; moreover, assuming inequality (a) its maximum is $-\left(l_{n-1}-\left(l_{1}+\cdots+l_{n-2}\right)\right)^{2}$. Using inequalities (b) and (c), it follows that in this case there are homeomorphisms $E_{2}(A) \simeq\left(S^{1}\right)^{n-1}$ and $M_{A} \simeq\left(S^{1}\right)^{n-2}$.

Inequality (b) implies that a subset $J \subset\{1, \ldots, n\}$ is short with respect to $\ell^{-}$ if and only if $J$ does not contain the index $n-1$. Thus

$$
\alpha_{k}\left(\ell^{-}\right)=\binom{n-2}{k} \text { for } k=0, \ldots, n-2 .
$$

By inequality (c) every subset $J \subset\{1, \ldots, n\}$ with $n \in J$ is long with respect to $\ell^{+}$. Thus $\alpha_{k}\left(\ell^{+}\right)=0$ for all $k$. Similarly, the numbers $\beta_{k}\left(\ell^{+}, \ell^{-}\right)$and $\beta_{k}\left(\ell^{-}, \ell^{+}\right)$all vanish. We see that the result of Theorem 4.1.2 is consistent with the homeomorphism $M_{A} \simeq\left(S^{1}\right)^{n-2}$.

Example 4.2.3. We now study connectedness of the spaces $M_{A}$. By Theorem 4.1.2, the zero Betti number of $M_{A}$ is

$$
\operatorname{rk} H_{0}\left(M_{A} ; \mathbf{Z}\right)=\alpha_{0}\left(\ell^{-}\right)-\beta_{0}\left(\ell^{+}, \ell^{-}\right)+\alpha_{n-3}\left(\ell^{+}\right)-\beta_{n-3}\left(\ell^{-}, \ell^{+}\right) .
$$

From the definition of the numbers $\alpha_{k}$ and $\beta_{k}$ we see that the difference $\alpha_{0}\left(\ell^{-}\right)-$ $\beta_{0}\left(\ell^{+}, \ell^{-}\right)$can assume the values zero or one. Moreover, if $\alpha_{0}\left(\ell^{-}\right)-\beta_{0}\left(\ell^{+}, \ell^{-}\right)=0$, then either the set $\{n\}$ is long with respect to $\ell^{-}$or the set $\{n-1\}$ is long with respect to $\ell^{+}$. Thus using the second part of Proposition 1.5.1, $\alpha_{0}\left(\ell^{-}\right)-\beta_{0}\left(\ell^{+}, \ell^{-}\right)=1$ if the space $M_{A}$ is non-empty.

The difference $\alpha_{n-3}\left(\ell^{+}\right)-\beta_{n-3}\left(\ell^{-}, \ell^{+}\right)$is the number of two-element subsets $J \subset$ $\{1, \ldots, n-1\}$ which are long with respect to $\ell^{+}$and satisfy one of the following two conditions: either (a) $n-1 \notin J$ or (b) $n-1 \in J$ and the set $J \cup\{n\}-\{n-1\}$ is long with respect to $\ell^{-}$. We claim that there is at most one two-element subset $J \subset\{1, \ldots n-1\}$ which is long with respect to $\ell^{+}$and satisfies (a) or (b). Thus the number $\alpha_{n-3}\left(\ell^{+}\right)-\beta_{n-3}\left(\ell^{-}, \ell^{+}\right)$can assume the values zero or one.

Due to the assumption $l_{1} \leq l_{2} \leq \cdots \leq l_{n-1}$, either $l_{n-1}$ or $l_{n}^{+}$is a maximal entry of $\ell^{+}$. Since a length vector admits at most one long two-element set not containing the index of a maximal entry, there can be at most one two-element subset
$J \subset\{1, \ldots n-1\}$ which is long with respect to $\ell^{+}$and satisfies condition (a), namely $J=\{n-3, n-2\}$. If the set $\{n-3, n-2\}$ is long with respect to $\ell^{+}$, then it is also long with respect to $\ell^{-}$. It follows that the set $\{n-1, n\}$ is short with respect to $\ell^{-}$, but then so is the set $\{n-2, n\}$. We conclude that in this case there are no two-element subsets $J \subset\{1, \ldots, n-1\}$ that are long with respect to $\ell^{+}$and satisfy condition (b).

Assume now that there is a two-element subset $J \subset\{1, \ldots, n-1\}$ which is long with respect to $\ell^{+}$and satisfies condition (b). Then the set $\{n-2, n\}$ is long with respect to $\ell^{-}$and therefore also long with respect to $\ell^{+}$. Thus in this case no two-element subset $J \subset\{1, \ldots, n-1\}$ which is long with respect to $\ell^{+}$satisfies condition (a).

It follows that the space $M_{A}$ has at most two connected components and is disconnected if and only if either the condition

$$
\begin{equation*}
\{n-3, n-2\} \text { is long w.r.t. } \ell^{+} \tag{4.1}
\end{equation*}
$$

or the two conditions

$$
\begin{equation*}
\{n-2, n-1\} \text { is long w.r.t. } \ell^{+} \text {and }\{n-2, n\} \text { is long w.r.t. } \ell^{-} \tag{4.2}
\end{equation*}
$$

are satisfied. One concludes:
Proposition 4.2.4. If the space $M_{A}$ is disconnected, then there exist three indices $1 \leq i<j<k \leq n$ so that for every length vector $\ell \in A$ the two-elements sets $\{i, j\}$, $\{i, k\}$ and $\{j, k\}$ are long with respect to $\ell$.

Proof. If condition (4.1) is satisfied, then indices $i, j, k$ with the properties as indicated in the claim of the Proposition are given by $i=n-3, j=n-2$ and $k=n-1$. In the case when the conditions of (4.2) are met, we may set $i=n-2, j=n-1$ and $k=n$.

Proposition 4.2.4 means that if the space $M_{A}$ is disconnected, then for each $\ell \in A$ there is a massive triangle (see Proposition 1.6.6). Using Proposition 1.6.6 with $d=2$, it follows that in this case for every $\ell \in A$ the space $E_{2}(\ell)$, and thus also the space $M_{\ell}$ is disconnected. We have shown:

Corollary 4.2.5. If the space $M_{A}$ is disconnected, then so are all the spaces $M_{\ell}$ where $\ell \in A$.

Example 4.2.6. The following example shows that the space $M_{A}$ may be connected although both ends $M_{\ell^{ \pm}}$are disconnected. Let $n=4, l_{1}=4, l_{2}=8, l_{3}=10$, $l_{4}^{-}=1$ and $l_{4}^{+}=12$. In this case the spaces $M_{\ell^{-}}$and $M_{\ell^{+}}$are disconnected because a massive triangle exists both for $\ell^{-}$as well as for $\ell^{+}$. However, the space $M_{A}$ is connected as neither (4.1) nor (4.2) is satisfied.

### 4.3 Telescopic Linkages and the Topological Hypothesis

In this section we discuss an application of the study of the topology of telescopic polygons motivated by the so-called Topological Hypothesis in the theory of phase transitions.

The Topological Hypothesis consists of the statement that phase transitions in thermodynamical systems are caused by changes in the topology of certain submanifolds in the configuration space (see e.g. [5], [35] and references therein).

We consider a system with a Hamiltonian

$$
H=\frac{1}{2} \sum_{j=1}^{N} p_{j}^{2}+V\left(q_{1}, \ldots, q_{N}\right) .
$$

It is known that at any given value of the inverse temperature $\beta$, the effective support of the canonical measure is close to an equipotential surface

$$
\sigma_{v}=\left\{q \in \Gamma_{N}: V(q)=v N\right\} .
$$

Here $\Gamma_{N}$ is the configuration space and $V$ the potential of the system.

The Topological Hypothesis states that the reason for the singular behaviour of
thermodynamic observables in phase transitions of the system are changes of the topology of the level sets $\Sigma_{v}$ or of the sublevels

$$
\begin{equation*}
\mathcal{M}_{v}=\left\{q \in \Gamma_{N}: V(q) \leq v N\right\} . \tag{4.3}
\end{equation*}
$$

In [16] a version of the Topological Hypothesis was proved for a class of short-range models. Other known results concern the asymptotic growth rate

$$
\begin{equation*}
\sigma(v)=\lim _{N \rightarrow \infty} \frac{1}{N} \ln \left|\chi\left(\mathcal{M}_{v}\right)\right| \tag{4.4}
\end{equation*}
$$

of the Euler characteristic of the sublevels. In many cases non-smoothness of the function $\sigma(v)$ detects the presence of a phase transition (see e.g. the exposition in [28]). In the literature there are also results of negative character concerning the Topological Hypothesis ([29],[38]).

We now show that the spaces $M_{A}$ of planar polygons with a telescopic segment studied in the previous section can be identified with the sublevels $\mathcal{M}_{v}$ of a known thermodynamical model.

We consider the anti-ferromagnetic mean-field XY-model ([6], [32]), which is characterized by the potential

$$
\begin{equation*}
V=\frac{1}{2 N} \sum_{j, k=1}^{N} \cos \left(\theta_{j}-\theta_{k}\right)-h \sum_{j=1}^{N} \theta_{j}, \tag{4.5}
\end{equation*}
$$

where $\theta_{i} \in[0,2 \pi]$ are angular parameters and $h>0$ is also referred to as an external magnetic field. The configuration space $\Gamma_{N}$ of the model is an $N$-torus $T^{N}$ and we write points $q \in \Gamma_{N}$ as $q=\left\{e^{i \theta_{1}}, \ldots, e^{i \theta_{N}}\right\}$.

Denoting

$$
\mathbf{m}=\frac{1}{N} \sum_{j=1}^{N} \exp i \theta_{j}
$$

and

$$
\mathbf{m}_{0}=-i h,
$$

one obtains

$$
\left|\mathbf{m}+\mathbf{m}_{0}\right|^{2}=\frac{2}{N} V+h^{2} .
$$

Thus the sublevel $\mathcal{M}_{v}$ defined by (4.3) can be identified as

$$
\begin{equation*}
\mathcal{M}_{v}=\left\{q:\left|\mathbf{m}+\mathbf{m}_{0}\right|^{2} \leq 2 v+h^{2}\right\} . \tag{4.6}
\end{equation*}
$$

The interval $\left(a_{h}, b_{h}\right)$ of variation of the parameter $v$ is given by

$$
b_{h}=h+1 / 2
$$

and

$$
a_{h}= \begin{cases}-\frac{h^{2}}{2} & \text { if } h \in(0,1] \\ -h+\frac{1}{2} & \text { if } h \in[1, \infty)\end{cases}
$$

Comparing (4.6) with the definition of the space $M_{A}$ of planar telescopic polygons, one obtains:

Proposition 4.3.1. The space $\mathcal{M}_{v}$ defined by (4.3) is homeomorphic to the space $M_{A}$ of planar polygons with $N+1$ segments of fixed lengths $l_{1}=\cdots=l_{N}=1 / N$, $l_{N+1}=h$, and a telescopic segment whose length varies in the interval $\left[0,\left(2 v+h^{2}\right)^{1 / 2}\right]$. Our goal is to study the total Betti numbers

$$
\begin{equation*}
b\left(\mathcal{M}_{v}\right)=\sum_{k=0}^{N+2} b_{k}\left(\mathcal{M}_{v}\right) \tag{4.7}
\end{equation*}
$$

where $b_{k}\left(\mathcal{M}_{v}\right)=\operatorname{rk} H_{k}\left(\mathcal{M}_{v} ; \mathbf{Z}\right)$, and their exponential growth rate

$$
\begin{equation*}
\tau(v)=\lim _{N \rightarrow \infty} \frac{1}{N} \ln b\left(\mathcal{M}_{v}\right) \tag{4.8}
\end{equation*}
$$

We want to apply the identification given in Proposition 4.3.1 of the sublevels 4.3) with the configuration spaces of a planar telescopic linkage. The formulae of Proposition 4.1.2 cannot be used to compute the homology groups in the case of the telescopic linkage defined in Proposition 4.3.1: Proposition 4.1.2 only applies in the case of a telescopic segment whose length varies between two positive numbers. However, the method of proof of Proposition 4.1 .2 can be adapted to compute the Betti numbers of the sublevels $\mathcal{M}_{v}$. We will show:

Proposition 4.3.2. Let $h>0$ and $v \in\left(a_{h}, b_{h}\right)$. The exponential growth rate of the total Betti number (4.7) is

$$
\tau(v)=\left\{\begin{array}{cc}
-p_{v} \ln p_{v}-\left(1-p_{v}\right) \ln \left(1-p_{v}\right) & \text { if } v \leq 0  \tag{4.9}\\
\ln 2 & \text { if } v \geq 0
\end{array}\right.
$$

Here $p_{v}=\frac{1}{2}\left(\left(2 v+h^{2}\right)^{1 / 2}-h+1\right)$.

Proposition 4.3.2 shows that the function $\tau(v)$ and its first derivative are continuous at $v=0$, however the second derivative is discontinuous at that point. In light of the Topological Hypothesis, it is an interesting question how this result, obtained purely by topological methods, is reflected by the physics of the model.

### 4.4 Proof of Theorem 4.1.2

The space $M_{A}$ is a subset of

$$
W=\left\{\left(u_{1}, \ldots, u_{n-1}\right) \in S^{1} \times \cdots \times S^{1}\right\} / S O(2) \simeq T^{n-2}
$$

We can view $W$ as the space of all shapes of a planar robot arm, i.e. configurations viewed up to rotations (compare with Section 1.2).

Similarly to the proof of Theorem 3.1.1, consider the function $f_{\ell}: W \rightarrow \mathbb{R}$ given by

$$
f_{\ell}\left(u_{1}, \ldots, u_{n-1}\right)=-\left|\sum_{j=1}^{n-1} l_{j} u_{j}\right|^{2}
$$

The space $M_{A}$ is the preimage $f_{\ell}^{-1}[a, b]$, where

$$
a=-\left(l_{n}^{+}\right)^{2} \text { and } b=-\left(l_{n}^{-}\right)^{2} .
$$

Denote

$$
W^{a}=f_{\ell}^{-1}(-\infty, a], W^{b}=f_{\ell}^{-1}(-\infty, b] \text { and } W^{[a, b]}=f_{\ell}^{-1}[a, b] .
$$

Our goal is to compute the homology groups of $W^{[a, b]}=M_{A}$. The computation will use an explicit description of the homology groups of the manifolds $W^{a}$ and $W^{b}$ which follows from the results of [15] (see also Corollary 1.19 in [7]).

For every subset $J \subset\{1, \ldots, n\}$, denote by $W_{J} \subset W$ the submanifold consisting of those tuples $\left(u_{1}, \ldots, u_{n}\right) \in W$, so that $u_{i}=u_{j}$ for all $i, j \in J$. Each manifold $W_{J}$ is diffeomorphic to a torus of dimension $n-1-|J|$. Moreover, $W_{J}$ is contained in $W^{a}$ if and only if the set $J$ is long with respect to $\ell^{+}$. Similarly, $W_{J} \subset W^{b}$ if and
only if $J$ is long with respect to $\ell^{-}$.

We choose orientations of $W$ and of the submanifolds $W_{J}$ as follows. For $j=$ $1, \ldots, n-1$, denote by $e_{j}$ the vector field on the torus $T^{n-1}$ which is tangent to the $j$ th circle and rotates in the positive direction. If $e_{1}^{\prime}, \ldots, e_{n-1}^{\prime}$ denote the images of $e_{1}, \ldots, e_{n-1}$ under the projection $T^{n-1} \rightarrow T^{n-1} / S O(2)=W$, then the vector fields $e_{1}^{\prime}, \ldots, e_{n-1}^{\prime}$ generate at every point the tangent space to $W$ and satisfy $e_{1}^{\prime}+\cdots+e_{n-1}^{\prime}=0$. We orient $W$ by defining the basis $e_{2}^{\prime}, \ldots, e_{n-1}^{\prime}$ to be positive.

Given a subset $J \subset\{1, \ldots, n\}$, let $\bar{J}=\left\{k_{1}, \ldots, k_{r}\right\}, k_{1}<\cdots<k_{r}$ be the complement of $J$, where $r=n-1-|J|$. The vector fields $e_{k_{1}}^{\prime}, \ldots, e_{k_{r}}^{\prime}$ form a basis of the tangent space of $W_{J}$ at every point. We orient $W_{J}$ so that this basis is positive.

Proposition 4.4.1 ([15]). Let $0 \leq k \leq n-2$. The homology classes of all the submanifolds $W_{J}$, where $J \subset\{1, \ldots, n-1\}$ is a subset of cardinality $|J|=n-1-k$ which is long with respect to $\ell^{+}$, form a free basis of $H_{k}\left(W^{a} ; \mathbf{Z}\right)$. Similarly, the classes of the submanifolds $W_{J}$ so that $J \subset\{1, \ldots, n-1\},|J|=n-1-k$ and $J$ is long with respect to $\ell^{-}$, form a free basis of $H_{k}\left(W^{b} ; \mathbf{Z}\right)$.

It follows from Proposition 4.4.1 that

$$
\operatorname{rk} H_{k}\left(W^{a} ; \mathbf{Z}\right)=\alpha_{k}\left(\ell^{+}\right) \text {and } \operatorname{rk} H_{k}\left(W^{b} ; \mathbf{Z}\right)=\alpha_{k}\left(\ell^{-}\right)
$$

where $\alpha_{k}\left(\ell^{+}\right)$is the number of all subsets $J \subset\{1, \ldots, n-1\}$ of cardinality $|J|=$ $n-1-k$ which are long with respect to $\ell^{+}$(see Section 1.4).

Consider the homological exact sequence of the pair $\left(W^{b}, W^{[a, b]}\right)$ :

$$
\begin{aligned}
\cdots \rightarrow H_{k+1}\left(W^{b}, W^{[a, b]} ; \mathbf{Z}\right) & \rightarrow H_{k}\left(W^{[a, b]} ; \mathbf{Z}\right) \\
& \rightarrow H_{k}\left(W^{b} ; \mathbf{Z}\right) \xrightarrow{j_{k}} H_{k}\left(W^{b}, W^{[a, b]} ; \mathbf{Z}\right) \rightarrow \ldots
\end{aligned}
$$

By Proposition 4.4.1, the integral homology groups of the spaces $W^{a}$ and of $W^{b}$ are free abelian. Thus using excision, Poincaré-Lefschetz duality and the universal coefficient theorem,

$$
\begin{equation*}
H_{k}\left(W^{b}, W^{[a, b]} ; \mathbf{Z}\right) \simeq H^{n-2-k}\left(W^{a} ; \mathbf{Z}\right) \simeq\left(H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)\right)^{*} \tag{4.10}
\end{equation*}
$$

where

$$
\left(H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)\right)^{*}=\operatorname{Hom}\left(H_{n-2-k}\left(\left(W^{a} ; \mathbf{Z}\right)\right), \mathbf{Z}\right) .
$$

Consider the intersection form

$$
\begin{equation*}
H_{k}\left(W^{b} ; \mathbf{Z}\right) \otimes H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right) \rightarrow \mathbf{Z} \tag{4.11}
\end{equation*}
$$

Under the identifications of 4.10, the homomorphism

$$
H_{k}\left(W^{b} ; \mathbf{Z}\right) \rightarrow\left(H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)\right)^{*}
$$

associated to the bilinear form (4.11) coincides with

$$
j_{k}: H_{k}\left(W^{b} ; \mathbf{Z}\right) \rightarrow H_{k}\left(W^{b}, W^{[a, b]} ; \mathbf{Z}\right)
$$

There is a short exact sequence

$$
\begin{equation*}
0 \rightarrow \operatorname{coker}\left(j_{k+1}\right) \rightarrow H_{k}\left(W^{[a, b]} ; \mathbf{Z}\right) \rightarrow \operatorname{ker}\left(j_{k}\right) \rightarrow 0 \tag{4.12}
\end{equation*}
$$

It $r_{k}$ denotes the rank of the intersection form 4.11), then

$$
r_{k}+\operatorname{rk} \operatorname{ker}\left(j_{k}\right)=\operatorname{rk} H_{k}\left(W^{b} ; \mathbf{Z}\right)
$$

and

$$
r_{k}+\operatorname{rk} \operatorname{coker}\left(j_{k}\right)=\operatorname{rk} H_{k}\left(W^{b}, W^{[a, b]} ; \mathbf{Z}\right)=\operatorname{rk} H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)
$$

Together with 4.12), it follows that

$$
\begin{gathered}
\operatorname{rk} H_{k}\left(M_{A} ; \mathbf{Z}\right)=\operatorname{rk} H_{k}\left(W^{[a, b]} ; \mathbf{Z}\right) \\
=\operatorname{rk} H_{k}\left(W^{b} ; \mathbf{Z}\right)+\operatorname{rk} H_{n-3-k}\left(W^{a} ; \mathbf{Z}\right)-r_{k}-r_{k+1} \\
=\alpha_{k}\left(\ell^{-}\right)+\alpha_{n-3-k}\left(\ell^{+}\right)-r_{k}-r_{k+1} .
\end{gathered}
$$

Evidently, $\operatorname{ker}\left(j_{k}\right)$ is free abelian. Thus the short exact sequence 4.12) splits and the homology group $H_{k}\left(M_{A} ; \mathbf{Z}\right)$ is torsion-free if and only if so is the cokernel of the homomorphism $j_{k+1}$.

In order to compute the numbers $r_{k}$, we describe the intersection form 4.11. For this purpose, write $H_{k}\left(W^{b} ; \mathbf{Z}\right)$ as a direct sum

$$
\begin{equation*}
H_{k}\left(W^{b} ; \mathbf{Z}\right)=A_{k}^{b} \oplus B_{k}^{b} \oplus C_{k}^{b} \tag{4.13}
\end{equation*}
$$

of free abelian groups as follows:

- The subgroup $A_{k}^{b}$ is generated by the homology classes of all the submanifolds $W_{J}$ where $J \subset\{1, \ldots, n-1\},|J|=n-1-k, J$ is long with respect to $\ell^{-}$ and the set $\widehat{J}$ obtained from $J$ by removing the maximal index lying in $J$ and adding the index $n$ is long with respect to $\ell^{+}$.
- We define $B_{k}^{b}$ as the subgroup generated by the classes of the submanifolds $W_{J}$ so that $J \subset\{1, \ldots, n-1\},|J|=n-1-k, J$ is long with respect to $\ell^{-}, n-1 \in J$ and $\widehat{J}$ is short with respect to $\ell^{+}$(note that in this case $\left.\widehat{J}=J-\{n-1\} \cup\{n\}\right)$.
- The subgroup $C_{k}^{b}$ is generated by the homology classes of all the submanifolds $W_{J}$ where $J \subset\{1, \ldots, n-2\},|J|=n-1-k, J$ is long with respect to $\ell^{-}$ and $\widehat{J}$ is short with respect to $\ell^{+}$.

We write the homology group $H_{k}\left(W^{a} ; \mathbf{Z}\right)$ as a direct sum

$$
\begin{equation*}
H_{k}\left(W^{a} ; \mathbf{Z}\right)=A_{k}^{a} \oplus B_{k}^{a} \oplus C_{k}^{a}, \tag{4.14}
\end{equation*}
$$

of free abelian groups defined as above, but with the roles of $\ell^{-}$and $\ell^{+}$interchanged. Thus

- $A_{k}^{a}$ is generated by the classes $\left[W_{J}\right]$ so that $J \subset\{1, \ldots, n-1\},|J|=n-1-k$, $J$ is long with respect to $\ell^{+}$and $\widehat{J}$ is long with respect to $\ell^{-}$.
- $B_{k}^{a}$ is subgroup generated by the classes $\left[W_{J}\right]$ so that $J \subset\{1, \ldots, n-1\}$, $|J|=n-1-k, J$ is long with respect to $\ell^{+}, n-1 \in J$ and $\widehat{J}$ is short with respect to $\ell^{-}$.
- $C_{k}^{a}$ is generated by the classes $\left[W_{J}\right]$ so that $J \subset\{1, \ldots, n-2\},|J|=n-1-k$, $J$ is long with respect to $\ell^{+}$and $\widehat{J}$ is short with respect to $\ell^{+}$.

Counting the numbers of the basis elements of the groups $B_{k}^{b}$ and $B_{k}^{a}$ and comparing with the combinatorial quantities introduced in Section 1.4, one obtains

$$
\operatorname{rk} B_{k}^{b}=\beta_{k}\left(\ell^{+}, \ell^{-}\right) \text {and rk } B_{k}^{a}=\beta_{k}\left(\ell^{-}, \ell^{+}\right) .
$$

Thus to establish the claim of Theorem 4.1.2, it suffices to show that the cokernel of the homomorphism $j_{k}$ is torsion-free and the rank of its image coincides with the
rank of $B_{k}^{b}$.

We now evaluate the intersection form (4.11) on the direct summands of the splittings (4.13) and (4.14). If $J, K \subset\{1, \ldots, n-1\}$ are subsets with $|J|+|K|=n$, then the submanifolds $W_{J}$ and $W_{K}$ of $W$ have complimentary dimensions and the intersection number of the homology classes $\left[W_{J}\right]$ and $\left[W_{K}\right]$ is

$$
\left[W_{J}\right] \cdot\left[W_{K}\right]= \begin{cases} \pm 1 & \text { if }|J \cap K|=1 \\ 0 & \text { if }|J \cap K|>1\end{cases}
$$

Let $\left[W_{J}\right] \in A_{k}^{b}$ and $\left[W_{K}\right] \in H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)$. Suppose that the intersection number $\left[W_{J}\right] \cdot\left[W_{K}\right]$ is non-zero. Then the set $K$ is obtained from the complement of $J$ in $\{1, \ldots, n-1\}$ by adding an element $j \in J$. Since the set $K$ is long with respect to $\ell^{+}$, its complement

$$
\bar{K}=\{1, \ldots, n\}-K
$$

is short with respect to $\ell^{+}$. As $\bar{K}=J-\{j\} \cup\{n\}$, it follows that the set $\widehat{J}$ obtained from $J$ by removing its largest element is also short with respect to $\ell^{+}$. This is a contradiction to the definition of the subgroup $A_{k}^{b}$. We see that the intersection number $\left[W_{J}\right] \cdot\left[W_{K}\right]$ of any two classes $\left[W_{J}\right] \in A_{k}^{b}$ and $\left[W_{K}\right] \in H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)$ vanishes. An analogous argument shows that $\left[W_{J}\right] \cdot\left[W_{K}\right]=0$ for all $\left[W_{J}\right] \in H_{k}\left(W^{b} ; \mathbf{Z}\right)$ and $\left[W_{K}\right] \in A_{n-2-k}^{a}$.

Consider now the case $\left[W_{J}\right] \in B_{k}^{b}$ and $\left[W_{K}\right] \in B_{n-2-k}^{a}$. As both sets $J$ and $K$ contain the index $n-1$, the intersection number $\left[W_{J}\right] \cdot\left[W_{K}\right]$ is non-zero if and only if the set $J$ is obtained from the complement $\bar{K}$ by removing the index $n$ and adding the index $n-1$. Examining the definitions of the subgroups $B_{k}^{b}$ and $B_{n-2-k}^{a}$, one concludes that for every class $\left[W_{J}\right] \in B_{k}^{b}$, there is a unique basis element $\left[W_{K}\right] \in B_{n-2-k}^{a}$ with $\left[W_{J}\right] \cdot\left[W_{K}\right] \neq 0$ (given by $K=\bar{J}-\{n\} \cup\{n-1\}$ ) and the intersection number with that basis element is $\left[W_{J}\right] \cdot\left[W_{K}\right]= \pm 1$. It follows that the restriction of the intersection form (4.11) to $B_{k}^{b} \otimes B_{n-2-k}^{a}$ is nondegenerate.

The intersection number $\left[W_{J}\right] \cdot\left[W_{K}\right]$ vanishes if $\left[W_{J}\right] \in C_{k}^{b}$ and $\left[W_{K}\right] \in C_{n-2-k}^{a}$.

Indeed, since in this case neither the set $J$ nor the set $K$ contains the index $n-1$, the two sets have at least two elements in common.

We define for each basis element $\left[W_{J}\right] \in C_{k}^{b}$ an element $Y_{J} \in H_{k}\left(W^{b} ; \mathbf{Z}\right)$ by

$$
\begin{equation*}
Y_{J}=\left[W_{J}\right]-\sum_{I} \frac{\left[W_{J}\right] \cdot\left[W_{I^{\prime}}\right]}{\left[W_{I}\right] \cdot\left[W_{I^{\prime}}\right]}\left[W_{I}\right], \tag{4.15}
\end{equation*}
$$

where the sum is over all the basis elements of the subgroup $B_{k}^{b}$ and $I^{\prime}$ denotes the set

$$
I^{\prime}=\bar{I}-\{n\} \cup\{n-1\}
$$

Here $\bar{I}$ is the complement of $I$ in $\{1, \ldots, n\}$.

It follows from 4.15) that the intersection number $Y_{J} \cdot\left[W_{K}\right]$ is zero for all $\left[W_{K}\right] \in$ $A_{n-2-k}^{a} \oplus B_{n-2-k}^{a}$. Let us show that the intersection number also vanishes in the case $\left[W_{K}\right] \in C_{n-2-k}^{a}$.

The non-zero summands on the right-hand side of 4.15) correspond to sets $I$ of the form

$$
\begin{equation*}
I=J-\{j\} \cup\{n-1\}, \tag{4.16}
\end{equation*}
$$

where $j \in J$. We denote the right-hand side of (4.16) by $I_{j}=J-\{j\} \cup\{n-1\}$.

If $J \subset\{1, \ldots, n-2\}$ is long with respect to $\ell^{-}$and $\widehat{J}$ is short with respect to $\ell^{+}$, then for every $j \in J$ the set $I_{j}$ is long with respect to $\ell^{-}$and the set $\widehat{I}_{j}$ is short with respect to $\ell^{+}$. Thus

$$
\begin{equation*}
Y_{J}=\left[W_{J}\right]-\sum_{j \in J} \frac{\left[W_{J}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}{\left[W_{I_{j}}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}\left[W_{I_{j}}\right] . \tag{4.17}
\end{equation*}
$$

For $\left[W_{K}\right] \in C_{n-2-k}^{a}$, the intersection number $Y_{J} \cdot\left[W_{K}\right]$ can be expressed as

$$
\begin{align*}
Y_{J} \cdot\left[W_{K}\right] & =\left[W_{J}\right] \cdot\left[W_{K}\right]-\sum_{j \in J} \frac{\left[W_{J}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}{\left[W_{I_{j}}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}\left(\left[W_{I_{j}}\right] \cdot\left[W_{K}\right]\right) \\
& =\sum_{j \in J} \frac{\left[W_{J}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}{\left[W_{I_{j}}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}\left(\left[W_{I_{j}}\right] \cdot\left[W_{K}\right]\right) . \tag{4.18}
\end{align*}
$$

If $\left|K \cap I_{j}\right|=1$ for some $j \in J$, then $|J \cap K|=2$. Thus in the case $|J \cap K|>2$ every term in the sum on the right-hand side of 4.18$)$ is zero and hence $Y_{J} \cdot\left[W_{K}\right]=0$.

Assume now that $|J \cap K|=2$. Let $J \cap K=\{i, j\}$. Then one obtains

$$
Y_{J} \cdot\left[W_{K}\right]=-\nu_{i}-\nu_{j},
$$

where

$$
\nu_{i}=\frac{\left[W_{J}\right] \cdot\left[W_{I_{i}^{\prime}}\right]}{\left[W_{I_{i}}\right] \cdot\left[W_{I_{i}^{\prime}}\right]}\left(\left[W_{I_{i}}\right] \cdot\left[W_{K}\right]\right)
$$

and where $\nu_{j}$ is defined analogously, but with the index $i$ replaced by $j$. To prove that the intersection number $Y_{J} \cdot\left[W_{K}\right]$ vanishes, we must demonstrate that $\nu_{i}=-\nu_{j}$. This will be shown by a similar symmetry argument as was used in the proof of Theorems 3.1.3 and 3.1.5 in the preceding chapter.

Consider the homeomorphism $T^{n-1} \rightarrow T^{n-1}$ which interchanges the $i$ th and the $j$ th coordinate and the induced homeomorphism $\phi: W \rightarrow W$. The fact that the sets $J$ and $K$ contain the indices $i$ and $j$ implies that

$$
\begin{equation*}
\phi\left(W_{J}\right)=W_{J} \text { and } \phi\left(W_{K}\right)=W_{K} \tag{4.19}
\end{equation*}
$$

Moreover,

$$
\begin{equation*}
\phi\left(W_{I_{i}}\right)=W_{I_{j}}, \phi\left(W_{I_{j}}\right)=W_{I_{i}} \tag{4.20}
\end{equation*}
$$

and

$$
\begin{equation*}
\phi\left(W_{I_{i}^{\prime}}\right)=W_{I_{j}^{\prime}}, \phi\left(W_{I_{j}^{\prime}}\right)=W_{I_{i}^{\prime}} . \tag{4.21}
\end{equation*}
$$

Since $\phi$ reverses the orientation of $W$, for any two homology classes $x \in H_{k}(W ; \mathbf{Z})$, $y \in H_{n-2-k}(W ; \mathbf{Z})$,

$$
\begin{equation*}
\phi_{*}(x) \cdot \phi_{*}(y)=-x \cdot y \tag{4.22}
\end{equation*}
$$

As $\phi$ preserves the orientations of the submanifolds $W_{J}$ and $W_{K}$,

$$
\begin{equation*}
\phi_{*}\left(\left[W_{J}\right]\right)=\left[W_{J}\right] \text { and } \phi_{*}\left(\left[W_{K}\right]\right)=\left[W_{K}\right] . \tag{4.23}
\end{equation*}
$$

We compute

$$
\begin{equation*}
\nu_{i}=-\frac{\phi_{*}\left(\left[W_{J}\right]\right) \cdot \phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right)}{\phi_{*}\left(\left[W_{I_{i}}\right]\right) \cdot \phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right)}\left(\phi_{*}\left(\left[W_{\left.I_{i}\right]}\right]\right) \cdot \phi_{*}\left(\left[W_{K}\right]\right)\right) \tag{4.24}
\end{equation*}
$$

$$
\begin{equation*}
=-\frac{\left[W_{J}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}{\left[W_{I_{j}}\right] \cdot\left[W_{I_{j}^{\prime}}\right]}\left(\left[W_{I_{j}}\right] \cdot\left[W_{K}\right]\right)=-\nu_{j} . \tag{4.25}
\end{equation*}
$$

Here (4.24) follows from (4.22) and (4.25) is obtained with the help of (4.19), (4.21) and (4.23). We note that by (4.19) and 4.21),

$$
\begin{equation*}
\phi_{*}\left(\left[W_{I_{i}}\right]\right)= \pm\left[W_{I_{j}}\right] \text { and } \phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right)= \pm\left[W_{I_{j}^{\prime}}\right] . \tag{4.26}
\end{equation*}
$$

One observes that since each of the classes $\phi_{*}\left(\left[W_{I_{i}}\right]\right)$ and $\phi_{*}\left(\left[W_{I_{i}^{\prime}}\right]\right)$ appears twice on the right-hand side of $(4.24)$, the signs from the right-hand sides of (4.26) cancel.

We can now complete the proof of Theorem4.1.2. If $\widetilde{C}_{k}^{b} \subset H_{k}\left(W^{b} ; \mathbf{Z}\right)$ denotes the subgroup generated by all the homology classes $Y_{J}$ corresponding to basis elements $\left[W_{J}\right] \in C_{k}^{b}$, then there is a direct sum decomposition

$$
H_{k}\left(W^{b} ; \mathbf{Z}\right)=A_{k}^{b} \oplus B_{k}^{b} \oplus \widetilde{C}_{k}^{b}
$$

We have shown that the homomorphism

$$
j_{k}: H_{k}\left(W^{b} ; \mathbf{Z}\right) \rightarrow H_{k}\left(W^{b}, W^{[a, b]}\right) \simeq\left(H_{n-2-k}\left(W^{a} ; \mathbf{Z}\right)\right)^{*}
$$

vanishes on $A_{k}^{b} \oplus \widetilde{C}_{k}^{b}$ and the restriction of $j_{k}$ to $B_{k}^{b}$ is a monomorphism onto a direct summand. It follows that the cokernel of the homomorphism $j_{k}$ is torsion-free and the rank of the image of $j_{k}$ coincides with the rank of $B_{k}^{b}$. This completes the proof.

### 4.5 Proof of Proposition 4.3.2

The claim of Proposition 4.3 .2 will be concluded from the following result:
Proposition 4.5.1. Let $A$ be the metric data of the polygonal telescopic linkage defined in Proposition 4.3.1. Denote

$$
c_{k}=\left\{\begin{array}{cl}
\binom{N}{k} & \text { if } \quad 0 \leq k \leq p_{v} N  \tag{4.27}\\
0 & \text { if } \quad p_{v} N<k \leq N
\end{array}\right.
$$

Moreover, define
and $d_{0}=d_{-1}=0$.

Let $N>h$. Then for $0 \leq k \leq N$, the homology group $H_{k}\left(M_{A} ; \mathbf{Z}\right)$ is free abelian with rank

$$
r k H_{k}\left(M_{A} ; \mathbf{Z}\right)=c_{k}+d_{N-1-k} .
$$

Proof of Proposition 4.3.2. Denote

$$
S_{k}^{N}=\sum_{0 \leq j \leq k}\binom{N}{j} \text { and } R_{k}^{N}=\sum_{0 \leq j<k}\binom{N}{j} .
$$

Combining Propositions 4.3.1 and 4.5.1, one obtains the following formula for the total Betti number of the sublevels $\mathcal{M}_{v}$ for $N>h$ :

$$
b\left(\mathcal{M}_{v}\right)=S_{p_{v} N}^{N}+R_{\left(1-h-p_{v}\right) N}^{N} .
$$

Assume first that $v \leq 0$. In this case $1-p_{v}-h \leq p_{v} \leq 1 / 2$ and hence

$$
\begin{equation*}
\binom{N}{\left\lfloor p_{v} N\right\rfloor}<b\left(\mathcal{M}_{v}\right)<2 S_{p_{v} N}^{N} \leq n\binom{N}{\left\lfloor p_{v} N\right\rfloor} . \tag{4.29}
\end{equation*}
$$

To further analyze the total Betti number, the following asymptotic formula for the binomial coefficients will be used (see [4], page 4):

$$
\begin{equation*}
\binom{n}{m} \sim(2 \pi)^{-1}\left(\frac{n}{m}\right)^{m}\left(\frac{n}{n-m}\right)^{n-m}\left(\frac{m(n-m)}{n}\right)^{-1 / 2} . \tag{4.30}
\end{equation*}
$$

This last asymptotic formula holds if $n, m \rightarrow \infty$ and $n-m \rightarrow \infty$. The notation $f(n) \sim g(n)$ means that $f(n) / g(n) \rightarrow 1$.

Using (4.30, one obtains:

$$
\begin{equation*}
\lim _{N \rightarrow \infty} \frac{1}{N} \ln \binom{N}{\left\lfloor p_{v} N\right\rfloor}=-p_{v} \ln p_{v}-\left(1-p_{v}\right) \ln \left(1-p_{v}\right) . \tag{4.31}
\end{equation*}
$$

The first part of (4.9) follows by combining (4.29) and (4.31).

Consider now the case $v \geq 0$. Here $p_{v} \geq 1 / 2$ and thus $S_{p_{v} N}^{N} \geq 2^{N-1}$. We obtain the estimate

$$
\begin{equation*}
2^{N-1} \leq b\left(\mathcal{M}_{v}\right) \leq 2^{N+1} \tag{4.32}
\end{equation*}
$$

The second part of (4.9) follows from 4.32).

Proof of Proposition 4.5.1. Denote by $\ell$ the length vector with entries

$$
\begin{equation*}
l_{1}=\cdots=l_{N}=\frac{1}{N}, l_{N+1}=h \text { and } l_{N+2}=\left(2 v+h^{2}\right)^{1 / 2} . \tag{4.33}
\end{equation*}
$$

Due to the assumption $N>h$, we have $l_{j} \leq l_{N+1}$ for $j=1, \ldots, N+1$.

Consider

$$
W=\left\{\left(u_{1} \ldots u_{N+1}\right) \in\left(S^{1}\right)^{N+1}\right\} / S O(2) \simeq T^{N}
$$

and the function $f_{\ell}: W \rightarrow \mathbb{R}$ defined in the previous section.

Let $A$ be the metric data of the telescopic linkage defined in Proposition 4.3.1. Using similar notation as in the proof of Proposition 4.1.2, define

$$
W^{a}=f_{\ell}^{-1}(-\infty, a], a=\left(2 v+h^{2}\right)^{1 / 2} .
$$

Consider the homology exact sequence of the pair $\left(W, W^{a}\right)$ :

$$
\cdots \rightarrow H_{k+1}\left(W, W^{a} ; \mathbf{Z}\right) \rightarrow H_{k}\left(W^{a} ; \mathbf{Z}\right) \xrightarrow{i_{k}} H_{k}(W ; \mathbf{Z}) \rightarrow H_{k}\left(W, W^{a} ; \mathbf{Z}\right) \rightarrow \ldots
$$

Using excision and Poincaré-Lefschetz duality,

$$
\begin{aligned}
H_{k+1}\left(W, W^{a} ; \mathbf{Z}\right) & \simeq H_{k+1}\left(M_{A}, \partial M_{A} ; \mathbf{Z}\right) \\
& \simeq H^{N-1-k}\left(M_{A} ; \mathbf{Z}\right) \simeq H^{N-1-k}\left(\mathcal{M}_{v} ; \mathbf{Z}\right) .
\end{aligned}
$$

Thus there is a short exact sequence

$$
\begin{equation*}
0 \rightarrow \operatorname{coker}\left(i_{k+1}\right) \rightarrow H^{N-1-k}\left(\mathcal{M}_{v} ; \mathbf{Z}\right) \rightarrow \operatorname{ker}\left(i_{k}\right) \rightarrow 0 \tag{4.34}
\end{equation*}
$$

By Proposition 4.4.1, there is a free basis of $H_{k}\left(W^{a} ; \mathbf{Z}\right)$ consisting of the homology classes $\left[W_{J}\right]$, where $J \subset\{1, \ldots, N+1\}$ is a subset of cardinality $|J|=N+1-k$ which is long with respect to $\ell$. Consider the direct sum decomposition

$$
\begin{equation*}
H_{k}\left(W^{a} ; \mathbf{Z}\right)=D_{k} \oplus E_{k}, \tag{4.35}
\end{equation*}
$$

where $D_{k}$ is the subgroup generated by the homology classes $\left[W_{J}\right]$ so that $J \subset$ $\{1, \ldots, N+1\},|J|=N+1-k, J$ is long with respect to $\ell$ and contains the index $N+1$. The subgroup $E_{k}$ is generated by the classes $\left[W_{J}\right]$ so that $J \subset\{1, \ldots, N+1\}$,
$|J|=N+1-k, J$ is long with respect to $\ell$ and $N+1 \notin J$.

The homology group $H_{k}(W ; \mathbf{Z})$ has a free basis consisting of all the classes [ $W_{J}$ ] where $J \subset\{1, \ldots, N+1\},|J|=N+1-k$ and $N+1 \in J$ (we refer to the previous section for the definition of the submanifolds $\left.W_{J}\right)$. We write $H_{k}(W ; \mathbf{Z})$ as a direct sum

$$
\begin{equation*}
H_{k}(W ; \mathbf{Z})=D_{k} \oplus F_{k}, \tag{4.36}
\end{equation*}
$$

of free abelian groups, where $D_{k}$ is defined as above and $F_{k}$ is the subgroup generated by the classes $\left[W_{J}\right]$ so that $J \subset\{1, \ldots, N+1\},|J|=N+1-k, N+1 \in J$ and so that $J$ is either short or median with respect to $\ell$.

The homomorphism

$$
i_{k}: H_{k}\left(W^{a} ; \mathbf{Z}\right) \rightarrow H_{k}(W ; \mathbf{Z})
$$

induced by inclusion restricts to the identity on $D_{k}$. Let us show that $i_{k}\left(E_{k}\right) \subset D_{k}$.

Consider an element [ $W_{J}$ ] of the specified basis of $E_{k}$. We compute

$$
\begin{equation*}
i_{k}\left(\left[W_{J}\right]\right)=\sum_{\left[W_{I}\right] \in D_{k}} \frac{\left[W_{J}\right] \cdot\left[W_{I^{\prime}}\right]}{\left[W_{I}\right] \cdot\left[W_{I^{\prime}}\right]}\left[W_{I}\right]+\sum_{\left[W_{K}\right] \in F_{k}} \frac{\left[W_{J}\right] \cdot\left[W_{K^{\prime}}\right]}{\left[W_{K}\right] \cdot\left[W_{K^{\prime}}\right]}\left[W_{K}\right] . \tag{4.37}
\end{equation*}
$$

Here $I^{\prime}$ denotes the set $\{1, \ldots, N+1\}-I \cup\{N+1\}$.

Suppose that for some class $\left[W_{K}\right] \in F_{k}$ coefficient of $\left[W_{K}\right]$ in the second sum on the right-hand side of (4.37) is non-zero. Then the sets $J$ and $K^{\prime}$ must have a unique common element $j \in\{1, \ldots, N+1\}$. Thus the set $K$ is obtained from $J$ by removing the index $j$ and adding the index $N+1$. Since $l_{j} \leq l_{N+1}$ and $J$ is long with respect to $\ell$, it follows that $K$ must also be long with respect to $\ell$. This contradicts the definition of the subgroup $F_{k}$. We conclude that the second sum on the righthand side of (4.37) vanishes identically for every class $\left[W_{J}\right] \in E_{k}$. Thus $i_{k}\left(E_{k}\right) \subset D_{k}$.

It follows from the above discussion that the ranks of the kernel and of the cokernel of $i_{k}$ coincide with the ranks of $E_{k}$ and of $F_{k}$ respectively. Moreover, the
cokernel of $i_{k}$ is torsion-free. Using the short exact sequence (4.34), we conclude that $H^{N-1-k}\left(\mathcal{M}_{v} ; \mathbf{Z}\right)$ is the free abelian group of rank

$$
\begin{equation*}
\operatorname{rk} H^{N-1-k}\left(\mathcal{M}_{v} ; \mathbf{Z}\right)=\operatorname{rk} E_{k}+\operatorname{rk} F_{k+1} . \tag{4.38}
\end{equation*}
$$

It remains to calculate the ranks of the subgroups $E_{k}$ and $F_{k+1}$. By definition, the rank of $E_{k}$ coincides with the number of subsets $J \subset\{1, \ldots, N+1\}$ of cardinality $|J|=N+1-k$ so that $N+1 \notin J$ and $J$ is long with respect to $\ell$. Examining (4.28) and 4.33), one finds rk $E_{k}=d_{k}$. The rank of $F_{k+1}$ is given by the number of subsets $J \subset\{1, \ldots, N+1\}$ so that $|J|=N-k, N+1 \in J$ and $J$ is either short or median with respect to $\ell$. Combining (4.27) and (4.33), one concludes that rk $F_{k+1}=c_{N-1-k}$. This completes the proof.

## Chapter 5

## Cohomology of Spaces of Polygons

In this chapter we show that the isomorphism type of the graded cohomology ring $H^{*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ determines the chamber of the length vector $\ell$ up to a permutation of the entries of $\ell$. This result means that the spaces $E_{d}(\ell)$ are classified by their $\mathrm{Z}_{2}$-cohomology rings.

### 5.1 The inverse Problem

It follows from Proposition 1.5 .3 that the homeomorphism type of the space $E_{d}(\ell)$ depends only on the orbit of the chamber of $\ell$ under the action of the symmetric group $\Sigma_{n}$. It is an interesting question whether topological invariants of the space $E_{d}(\ell)$ can be used to distinguish between different orbits.

In [40, K. Walker studied the planar polygon spaces $M_{\ell}=E_{2}(\ell) / S O(2)$. He conjectured that these spaces are classified by their cohomology rings, more precisely that if for two generic length vectors $\ell$ and $\ell^{\prime}$ the spaces $M_{\ell}$ and $M_{\ell^{\prime}}$ have isomorphic cohomology rings, then $\ell$ and $\ell^{\prime}$ lie in the same chamber after a permutation of the entries. Walker's Conjecture was proved for a large class of length vectors in [12] and the remaining cases were resolved in [36]. A proof of an analogous result for the spaces $N_{\ell}=E_{3}(\ell) / S O(3)$ can also be found in [12].

We will show that for each $d \geq 2$ the spaces $E_{d}(\ell)$ satisfy an analogue of Walker's Conjecture. We first demonstrate that the Conjecture for the spaces $E_{2}(\ell)$ and cohomology with integral coefficients follows from the results mentioned above.

By Proposition 1.5.2, for every length vector $\ell$ there is a homeomorphism

$$
\begin{equation*}
E_{2}(\ell) \simeq S^{1} \times M_{\ell} \tag{5.1}
\end{equation*}
$$

On the other hand, if $\ell$ is generic, $0<\varepsilon<[\ell]$ and $(\varepsilon, \ell)$ denotes the length vector obtained by inserting $\varepsilon$ as the first entry of $\ell$, then the product $S^{1} \times M_{\ell}$ is homeomorphic to the space $M_{(\varepsilon, \ell)}$ :

$$
\begin{equation*}
S^{1} \times M_{\ell} \simeq M_{(\varepsilon, \ell)} \tag{5.2}
\end{equation*}
$$

(see Proposition 4.1 in [36], compare also with Proposition 1.6.5). Combining the two homeomorphisms (5.1) and (5.2), we find that if $\ell$ is generic, then the space $E_{2}(\ell)$ can be identified as

$$
\begin{equation*}
E_{2}(\ell) \simeq M_{(\varepsilon, \ell)} . \tag{5.3}
\end{equation*}
$$

Suppose now that for two generic length vectors $\ell, \ell^{\prime}$ the spaces $E_{2}(\ell)$ and $E_{2}\left(\ell^{\prime}\right)$ have isomorphic graded integral cohomology rings. Using the first part of Proposition 1.5.3, we can assume without loss of generality that $\ell$ and $\ell^{\prime}$ are ordered. Fix $0<\varepsilon<[\ell]$ and $0<\varepsilon^{\prime}<\left[\ell^{\prime}\right]$ sufficiently small, so that $(\varepsilon, \ell)$ and $\left(\varepsilon^{\prime}, \ell^{\prime}\right)$ are ordered as well. Using the homeomorphism (5.3) and Theorem 1.2 from [36], it follows that $(\varepsilon, \ell)$ and $\left(\varepsilon^{\prime}, \ell^{\prime}\right)$ lie in the same chamber after a permutation of the entries. Since the length vectors $(\varepsilon, \ell)$ and $\left(\varepsilon^{\prime}, \ell^{\prime}\right)$ are ordered, the second part of Lemma 1.3.4 shows that they lie in the same chamber, but then using Lemma 1.3 .6 so do the two length vectors $\ell$ and $\ell^{\prime}$. These arguments establish Walker's Conjecture for the spaces $E_{2}(\ell)$ as a consequence of the main result of [36].

We can now state the main result of this chapter.
Theorem 5.1.1. Let $\ell, \ell^{\prime}$ be two generic length vectors and let $d>2$. The following conditions are equivalent:

1. The spaces $E_{d}(\ell)$ and $E_{d}\left(\ell^{\prime}\right)$ are $O(d)$-equivariantly diffeomorphic;
2. There is an isomorphism

$$
H^{*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq H^{*}\left(E_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}_{2}\right)
$$

of graded rings;
3. There is a ring isomorphism

$$
H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq H^{(d-1) *}\left(E_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}_{2}\right) ;
$$

4. There is a permutation $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$, so that the length vectors $\sigma(\ell)$ and $\ell^{\prime}$ lie in the same chamber.

The proof of Theorem 5.1.1 uses a similar approach as the results in [12], with the Morse-Bott lacunary principle of Chapter 2 as a central new tool.

Using the results of Chapter 3 , it is not difficult to show that the homology groups of the space $E_{d}(\ell)$ in general do not determine the orbit of the chamber of $\ell$ under the action of the permutation group $\Sigma_{n}$. For example, consider the two length vectors

$$
\begin{equation*}
\ell=(1,2,2,2,4,4) \tag{5.4}
\end{equation*}
$$

and

$$
\begin{equation*}
\ell^{\prime}=(1,1,3,4,8,8) . \tag{5.5}
\end{equation*}
$$

Evidently, $\ell$ and $\ell^{\prime}$ are generic. Moreover, the numbers $a_{k}(\ell)$ and $a_{k}\left(\ell^{\prime}\right)$ coincide for all $k$. Thus by Theorem 3.1.1, the $\mathbf{Z}_{2}$-Betti numbers of spaces $E_{d}(\ell)$ and $E_{d}\left(\ell^{\prime}\right)$ are equal. Using Theorem 3.1.2, it follows that the integral homology groups of $E_{d}(\ell)$ and $E_{d}\left(\ell^{\prime}\right)$ are isomorphic if $d$ is even. However, $\ell$ and $\ell^{\prime}$ do not lie in the same chamber since the set $J=\{1,4,6\}$ is short with respect to $\ell$, but long with respect to $\ell^{\prime}$.

Since the length vectors $\ell$ and $\ell^{\prime}$ given by (5.4) and (5.5) are both ordered, it follows from the second part of Lemma 1.3.4 that there is no permutation $\sigma:\{1, \ldots, n\} \rightarrow$ $\{1, \ldots, n\}$ so that $\sigma(\ell)$ and $\ell^{\prime}$ lie in the same chamber. This example shows that to distinguish between different orbits of the $\Sigma_{n}$-action on the set if chambers, it
is necessary to use the multiplicative structure of the cohomology ring $H^{*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$.

The main step in the proof of Theorem 5.1.1 is the computation of the subring $H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \subset H^{*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$, whose result we now state. We again assume for convenience that $\ell$ is ordered. The general case follows by permuting the entries of $\ell$ and applying the first part of Proposition 1.5.3.

Proposition 5.1.2. Let $\ell$ be an ordered length vector and let $d>2$. There is an isomorphism of graded rings

$$
\begin{equation*}
H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq \Lambda_{d}\left(Z_{1}, \ldots, Z_{n}\right) / I \tag{5.6}
\end{equation*}
$$

where $\Lambda_{d}\left(Z_{1}, \ldots, Z_{n}\right)$ is the exterior algebra over $\mathbf{Z}_{2}$ on generators $Z_{1}, \ldots, Z_{n}$ of degree $d-1$ and $I \subset \Lambda_{d}\left(Z_{1}, \ldots, Z_{n}\right)$ is the ideal generated by all the monomials

$$
Z^{J}=Z_{j_{1}} \cdots Z_{j_{k}}
$$

so that $J=\left\{j_{1}, \ldots, j_{k}\right\} \subset\{1, \ldots, n-1\}$ and the set $J \cup\{n\}$ is long with respect to $\ell$.

### 5.2 Proof of Theorem 5.1.1

We now prove Theorem 5.1.1 assuming Proposition 5.1.2. The proof uses the following algebraic result of J. Gubeladze ([18]).

Given a commutative ring $R$, an ideal $I \subset R\left[Z_{1}, \ldots, Z_{n}\right]$ is called monomial if it is generated by elements of the form $X_{1}^{a_{1}} \cdots X_{m}^{a_{m}}, a_{i} \geq 0$.

Theorem 5.2.1 ([18]). Let $R$ be a commutative ring and $I \subset R\left[X_{1}, \ldots, X_{m}\right]$, $I^{\prime} \subset R\left[Y_{1}, \ldots, Y_{m^{\prime}}\right]$ two monomial ideals. Assume that $I \cap\left\{X_{1}, \ldots, X_{m}\right\}=\emptyset$, $I^{\prime} \cap\left\{Y_{1}, \ldots, Y_{m^{\prime}}\right\}=\emptyset$ and that there is an isomorphism

$$
R\left[X_{1}, \ldots, X_{m}\right] / I \simeq R\left[Y_{1}, \ldots, Y_{m^{\prime}}\right] / I^{\prime}
$$

of $R$-algebras.

Then $m=m^{\prime}$ and there is a bijection

$$
\left\{X_{1}, \ldots, X_{m}\right\} \rightarrow\left\{Y_{1}, \ldots, Y_{m^{\prime}}\right\}
$$

which maps $I$ to $I^{\prime}$.

Proof of Theorem 5.1.1. The implications (1) $\Longrightarrow(2) \Longrightarrow$ (3) are evident and the implication $(4) \Longrightarrow(1)$ follows from the third part of Proposition 1.5.3. It remains to establish the implication $(3) \Longrightarrow$ (4).

Let $\ell, \ell^{\prime}$ be two generic length vectors so that the rings $H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ and $H^{(d-1) *}\left(E_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}_{2}\right)$ are isomorphic and so that, in addition, $\ell$ and $\ell^{\prime}$ are both ordered. We will show that in this case $\ell$ and $\ell^{\prime}$ lie in the same chamber. Since every length vector may be obtained from an ordered length vector by a permutation of the entries, this will establish Theorem 5.1.1.

It follows from Proposition 5.1.2 that $H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq \mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{n}\right] / K$ and $H^{(d-1) *}\left(E_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}_{2}\right) \simeq \mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{n}\right] / K^{\prime}$, where $K$ is the ideal generated by the squares $Z_{j}^{2}, j=1, \ldots, n$ and the monomials $Z^{J}=Z_{j_{1}} \cdots Z_{j_{k}}$ so that $n \notin J=$ $\left\{j_{1}, \ldots, j_{k}\right\}$ and the set $J \cup\{n\}$ is long with respect to $\ell$. The monomial ideal $K^{\prime}$ is defined analogously, but with $\ell$ replaced by $\ell^{\prime}$.

For $j=1, \ldots, n-1$, we have $Z_{j} \in K$ if and only if the set $\{j, n\}$ is long with respect to $\ell$. Denote

$$
i=\max \{1 \leq j \leq n-1:\{j, n\} \text { is short or median w.r.t. } \ell\}
$$

and

$$
i^{\prime}=\max \left\{1 \leq j \leq n-1:\{j, n\} \text { is short or median w.r.t. } \ell^{\prime}\right\} .
$$

There is a ring isomorphism

$$
\begin{equation*}
H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq \mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{i}, Z_{n}\right] / I \tag{5.7}
\end{equation*}
$$

where $I \subset \mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{i}, Z_{n}\right]$ is the ideal generated by the squares $Z_{j}^{2}, j \in\{1, \ldots, i, n\}$ as well as the monomials $Z^{J}=Z_{j_{1}} \cdots Z_{j_{k}}$ so that $J=\left\{j_{1}, \ldots, j_{k}\right\} \subset\{1, \ldots, i\}$ and
$J \cup\{n\}$ is long with respect to $\ell$. We note that $Z_{j} \notin I$ for $j=1, \ldots, i$. The condition $Z_{n} \in I$ is equivalent to the one-element set $\{n\}$ being long with respect to $\ell$ and thus determines the chamber of the length vector $\ell$ uniquely up to permutation of its entries. Using the first part of Proposition 1.5.1, this case is uniquely characterized by the space $E_{d}(\ell)$ being empty. Thus we may assume that $Z_{n} \notin I$.

Similarly,

$$
\begin{equation*}
H^{(d-1) *}\left(E_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}_{2}\right) \simeq \mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{i^{\prime}}, Z_{n}\right] / I^{\prime} \tag{5.8}
\end{equation*}
$$

with the monomial ideal $I^{\prime}$ defined as above, but with $\ell$ replaced by $\ell^{\prime}$.

By (5.7) and (5.8), condition (3) of the theorem implies the existence of a ring isomorphism

$$
\begin{equation*}
\mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{i}, Z_{n}\right] / I \simeq \mathbf{Z}_{2}\left[Z_{1}, \ldots, Z_{i^{\prime}}, Z_{n}\right] / I^{\prime} \tag{5.9}
\end{equation*}
$$

Applying Theorem 5.2.1, one concludes from (5.9) that $i=i^{\prime}$ and that there exists a permutation $\sigma$ of $\{1, \ldots, i, n\}$ so that a subset $J \subset\{1, \ldots, i, n\}$ with $n \in J$ is long with respect to $\ell$ if and only if the set $\sigma(J)$ is long with respect to $\ell^{\prime}$.

We extend $\sigma$ to a permutation of $\{1, \ldots, n\}$ by defining

$$
\sigma(j)=j \text { for } j=i+1, \ldots, n-1
$$

Denote by $k$ the image $k=\sigma(n)$ and by $\alpha$ the transposition of the two indices $k$ and $n$. Let $\alpha(\ell)$ be the length vector obtained from $\ell$ by interchanging the entries with these indices.

Since for every $j \in\{i+1, \ldots, n-1\}$ the set $\{j, n\}$ is long with respect to both $\ell$ and $\ell^{\prime}$, the composition $\alpha \circ \sigma$ maps the two sets

$$
\mathcal{L}_{n}(\ell)=\{J \subset\{1, \ldots, n\}: n \in J \text { and } J \text { is long with respect to } \ell\}
$$

and

$$
\mathcal{L}_{n}(\alpha(\ell))=\{J \subset\{1, \ldots, n\}: n \in J \text { and } J \text { is long with respect to } \alpha(\ell)\}
$$

bijectively to each other. Since $(\alpha \circ \sigma)(n)=n$, applying the criterion of Corollary 1.3.3, we conclude that the length vectors $\ell$ and $\alpha\left(\ell^{\prime}\right)$ lie in the same chamber after a permutation of their entries. It follows that $\ell$ and $\ell^{\prime}$ also lie in the same chamber after a permutation of the entries. This completes the proof of Theorem 5.1.1.

### 5.3 Proof of Proposition 5.1.2

Proof of Proposition 5.1.2. We use notation from the proof of Theorem 3.1.1. Consider the cohomological exact sequence of the pair $\left(W, E_{d}(\ell)\right)$ :

$$
\cdots \rightarrow H^{(d-1) k}\left(W ; \mathbf{Z}_{2}\right) \xrightarrow{i^{k}} H^{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow H^{(d-1) k+1}\left(W, E_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow \ldots
$$

By the proof of Theorem 3.1.1, the non-vanishing homology groups of $W-E_{d}(\ell)$ are concentrated in dimensions which are multiples of $d-1$. Using Poincaré duality and excision,

$$
H^{(d-1) k+1}\left(W, E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq H_{(d-1)(n-k)-1}\left(W-E_{d}(\ell) ; \mathbf{Z}_{2}\right)=0
$$

Thus the homomorphism

$$
i^{k}: H^{(d-1) k}\left(W ; \mathbf{Z}_{2}\right) \rightarrow H^{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

induced by inclusion is surjective. On the other hand, from the exact sequence

$$
H^{(d-1) k}\left(W, E_{d}(\ell) ; \mathbf{Z}_{2}\right) \xrightarrow{h^{k}} H^{(d-1) k}\left(W ; \mathbf{Z}_{2}\right) \xrightarrow{i^{k}} H^{(d-1) k}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

and the commutative square

where the columns are Poincare duality maps, we see that the kernel of $i^{k}$ consists exactly of the Poincaré duals of the elements of the image of $j_{n-k}$.

For $j=1, \ldots, n$, denote by

$$
\pi_{j}:\left(S^{d-1}\right)^{n} \rightarrow S^{d-1}
$$

the projection to the $j$ th factor. We identify $H^{*}\left(W ; \mathbf{Z}_{2}\right)$ as the exterior algebra generated by the classes

$$
X_{j}=\pi_{j}^{*}\left[S^{d-1}\right] \in H^{d-1}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

where $\left[S^{d-1}\right] \in H^{d-1}\left(S^{d-1} ; \mathbf{Z}_{2}\right)$ is the generator. Then

$$
H^{(d-1) *}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq \Lambda\left(X_{1}, \ldots, X_{n}\right) / I
$$

for $I=\operatorname{ker}\left(i^{k}\right)$.

Using Corollary 3.5.6, the kernel of $i^{k}$ consists of the Poincare duals of all the classes $\left[V_{J}\right],\left[W_{J}\right] \in H_{(d-1) *}\left(W ; \mathbf{Z}_{2}\right)$ so that $J \subset\{1, \ldots, n\}$ is a long subset containing the index $n$. The Poincaré dual of the class $\left[V_{J}\right]$ is the product $X^{J}=X_{j_{1}} \cdots X_{j_{k}}$, $J=\left\{j_{1}, \ldots, j_{k}\right\}$. Next, we note that

$$
\begin{equation*}
\left[W_{J}\right]=\sum_{j \in J}\left[V_{J-\{j\}}\right] \tag{5.10}
\end{equation*}
$$

Indeed, denoting for $j=1, \ldots, n$ by $S_{j}^{d-1} \subset W$ the $j$ th factor of the product $W=\left(S^{d-1}\right)^{n}$, we see that $W_{J}$ may be identified with the product of the diagonal $\Delta \subset \Pi_{j \in J} S_{j}^{d-1}$ and $\Pi_{j \notin J} S_{j}^{d-1}$. Equation 5.10 now follows from the fact that the homology class of the diagonal in a product $S^{d-1} \times \cdots \times S^{d-1}$ is the sum of the homology classes of the factors.

It follows that the Poincaré dual of the class $\left[W_{J}\right]$ is

$$
P D\left(\left[W_{J}\right]\right)=\sum_{j \in J} X^{J-\{j\}} .
$$

We conclude that the kernel of $i^{k}$ is generated additively by all the monomials

$$
X^{J}=X_{j_{1}} \cdots X_{j_{k}}
$$

as well as the polynomials

$$
\sum_{j \in J} X^{J-\{j\}}
$$

so that the subset $J=\left\{j_{1}, \ldots, j_{k}\right\} \subset\{1, \ldots, n\}$ is long with respect to $\ell$ and contains the index $n$.

Let us consider the following change of variables: we define a basis $Z_{1}, \ldots, Z_{n}$ of $H^{*}\left(W ; \mathbf{Z}_{2}\right)$ by

$$
Z_{j}=X_{j}+X_{n}, j=1, \ldots, n-1
$$

and

$$
Z_{n}=X_{n}
$$

Then for $J=\left\{j_{1}, \ldots, j_{k}\right\} \subset\{1, \ldots, n\}$ the monomial $Z^{J}=Z_{j_{1}} \cdots Z_{j_{k}}$ can be expressed as

$$
Z^{J}= \begin{cases}X^{J} & \text { if } n \in J \\ X^{J}+\sum_{j \in J} X^{J-\{j\}} X_{n} & \text { if } n \notin J\end{cases}
$$

Thus if we denote for a subset $J \subset\{1, \ldots, n\}$ by $J^{\prime}$ the set $J-\{n\}$, then

$$
Z^{J^{\prime}}=\sum_{j \in J} X^{J-\{j\}} .
$$

We see that in this new basis $I \subset \Lambda_{d}\left(Z_{1}, \ldots, Z_{n}\right)$ is additively generated by all the monomials $Z^{J}$ so that either $n \in J$ and $J$ is long with respect to $\ell$, or $n \notin J$ and the set $J \cup\{n\}$ is long with respect to $\ell$. Thus a multiplicative basis for $I$ is given by all the monomials $Z^{J}$ so that $n \notin J$ and the set $J \cup\{n\}$ is long with respect to $\ell$. This completes the proof of Proposition 5.1.2.

## Chapter 6

## Conclusions

The study of polygon spaces is an exciting field where algebraic topology, Morse theory and combinatorics intertwine. In this thesis, we showed that the special properties of the robot arm distance map in higher dimensions lead to new insights in Morse-Bott theory as well as to results on the structure of the homology groups and of the cohomology rings of spaces $E_{d}(\ell)$ of polygons up to translations.

The results of Chapter 3 together with the previous work of M. Farber and D. Schuetz ([15]) give explicit expressions for the homology groups $H_{*}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ in the case where $d$ is even. The Morse-Bott lacunary principle of Chapter 2 also provides a method for computing the integral homology groups when $d$ is odd, however in this case it seems a much more difficult task to find explicit general expressions.

As an example, let us list the integral homology groups in the case where $\ell$ is generic and $n=5$. There are seven chambers (up to permutation of the entries of $\ell$ ) and the homology groups $H_{*}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ for $d$ odd are given below. (Only the groups $H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ for $p=d-2, p=d-1$ and $p=2 d-3$ are listed. The remaining groups $H_{p}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ can be recovered from the table using Theorem 3.1.2, Poincaré duality and the universal coefficient Theorem.)

| $\ell$ | $H_{d-2}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ | $H_{d-1}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ | $H_{2 d-3}\left(E_{d}(\ell) ; \mathbf{Z}\right)$ |
| :---: | :---: | :---: | :---: |
| $(1,1,1,1,5)$ | 0 | 0 | 0 |
| $(1,1,3,3,3)$ | $\mathbf{Z}_{2}$ | $\mathbf{Z} \oplus \mathbf{Z}$ | $\mathbf{Z}_{2} \oplus \mathbf{Z}_{2} \oplus \mathbf{Z}$ |
| $(1,1,1,1,3)$ | 0 | $\mathbf{Z}$ | 0 |
| $(1,2,2,2,4)$ | 0 | $\mathbf{Z} \oplus \mathbf{Z}$ | $\mathbf{Z}$ |
| $(1,1,2,2,3)$ | 0 | $\underset{3}{\oplus} \mathbf{Z}$ | $\mathbf{Z}_{2} \oplus \mathbf{Z}_{2}$ |
| $(1,1,1,2,2)$ | 0 | $\underset{4}{\oplus} \mathbf{Z}$ | $\mathbf{Z}_{2} \oplus \mathbf{Z}_{2} \oplus \mathbf{Z}_{4}$ |
| $(1,1,1,1,1)$ | 0 | $\underset{5}{\oplus} \mathbf{Z}$ | $\left(\underset{4}{\oplus} \mathbf{Z}_{2}\right) \oplus \mathbf{Z}_{3}$ |

It is an interesting problem for further research to study in detail the structure of the homology groups in the case where $d$ is odd. A first step in this direction is the torsion criterion of Theorem 3.1.5,

In Chapter 4, we considered configuration spaces of planar polygons in the case where one of the edges has variable length. We computed their homology groups and related our results to topological questions studied in thermodynamics. Interpreting spaces of telescopic polygons as energy sublevels of the anti-ferromagnetic mean-field XY model allows to obtain an explicit formulae for the Betti numbers of the sublevels. As an indicator of the presence of phase transitions, we studied the exponential growth rate of the total Betti number as opposed to the exponential growth rate of the Euler characteristic, which was considered in previous results. One may hope that using the total Betti number instead of the Euler characteristic provides a more sensitive tool for the study of different versions of the Topological Hypothesis.

In Chapter 5, we studied the inverse problem for the spaces $E_{d}(\ell)$ of polygons up to translations. We proved that the spaces are classified by their $\mathbf{Z}_{2}$-cohomology rings. This motivates further study of the spaces $E_{d}(\ell)$ as analogues in higher dimensions of $M_{\ell}$ and $N_{\ell}$.

Appendices

## Appendix A

## Spaces of polygonal Chains

In the main body of this thesis, the spaces $E_{d}(\ell)$ of polygons in Euclidean space $\mathbb{R}^{d}$ were studied. Denote by $p: E_{d}(\ell) \rightarrow S^{d-1}$ the restriction to $E_{d}(\ell) \subset W=\left(S^{d-1}\right)^{n}$ of the projection $\left(u_{1}, \ldots, u_{n}\right) \mapsto u_{n}$. For $e \in S^{d-1}$, the preimage $C_{d}(\ell)=p^{-1}(e)$ may be viewed as the space of polygons up to translations, where the direction of the edge $l_{n}$ is fixed. The spaces $C_{d}(\ell)$ were studied in [20], [21] and in [13].

In the current appendix, we gather basic relationships between the spaces $E_{d}(\ell)$ and $C_{d}(\ell)$. We also show that for $d \neq 3$, the graded isomorphism type of the $\mathbf{Z}_{2^{-}}$ cohomology ring of the space $C_{d}(\ell)$ is invariant under arbitrary permutations of the entries of $\ell$.

## A. 1 Spaces of polygonal Chains

We recall from Section 1 the notation $W=\left(S^{d-1}\right)^{n}$. Fix $e \in S^{d-1}$ and consider the subspace

$$
W^{\prime}=\left\{\left(u_{1}, \ldots, u_{n}\right) \in W: u_{n}=-e\right\} \subset W .
$$

One defines $C_{d}(\ell) \subset W^{\prime}$ as the intersection $C_{d}(\ell)=E_{d}(\ell) \cap W^{\prime}$. There is an action on $C_{d}(\ell)$ of the subgroup $O(d-1) \subset O(d)$ consisting of those elements of the orthogonal group $O(d)$, which fix the vector $e$.

The following properties of the spaces $C_{d}(\ell)$ were established in [20] and [21].
Proposition A.1.1. ([20],[21])

1. For every generic length vector $\ell$, the space $C_{d}(\ell)$ is a closed oriented manifold of dimension

$$
\operatorname{dim} C_{d}(\ell)=(d-1)(n-2)-1
$$

2. If $\ell$ and $\ell^{\prime}$ are generic and $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ is a permutation which fixes the index $n$, then the spaces $C_{d}(\ell)$ and $C_{d}(\sigma(\ell))$ are $O(d-1)$-equivariantly diffeomorphic.
3. Let $\ell$ be a generic length vector and let $0<\varepsilon<[\ell]$ (see Section 1.3 for the definition of the quantity $[\ell]$ ). Then there is a diffeomorphism

$$
C_{d}(\varepsilon, \ell) \simeq S^{d-1} \times C_{d}(\ell)
$$

Here $(\varepsilon, \ell)$ is the length vector obtained from $\ell$ by inserting $\varepsilon$ as the first entry.

The following proposition states basic relationships between the spaces $E_{d}(\ell)$ and $C_{d}(\ell)$.

Proposition A.1.2. 1. For every length vector $\ell$ there is a fibration

2. Let $\ell$ be a generic length vector and let $0<\varepsilon<[\ell]$. There is a diffeomorphism

$$
E_{d}(\ell) \simeq C_{d}(\ell, \varepsilon)
$$

Here $(\ell, \varepsilon)$ denotes the length vector obtained from $\ell$ by inserting $\varepsilon$ as the last entry.

Proof. To prove the first part of the proposition, let $e \in S^{d-1}$ and consider an open neighbourhood $e \in U \subset S^{d-1}$ and a section $\psi: U \rightarrow S O(d)$ of the bundle
$S O(d) \rightarrow S^{d-1}$. We define a local trivialization of $p: E_{d}(\ell) \rightarrow S^{d-1}$ by mapping $\left(e^{\prime}, u\right) \in U \times C_{d}(\ell)$ to

$$
\left(\psi\left(e^{\prime}\right) u_{1}, \ldots, \psi\left(e^{\prime}\right) u_{n-1},-\psi\left(e^{\prime}\right) e\right) \in E_{d}(\ell) \subset W
$$

where $u=\left(u_{1}, \ldots, u_{n-1},-e\right) \in C_{d}(\ell) \subset W^{\prime}$. This defines the structure of a locally trivial fibre bundle.

To prove the second assertion, consider the map $G:\left(\mathbb{R}^{d}\right)^{n} \rightarrow \mathbb{R}^{n} \times \mathbb{R}^{d}$,

$$
G\left(v_{1}, \ldots, v_{n}\right)=\left(\left|v_{1}\right|,\left|v_{2}-v_{1}\right|, \ldots,\left|v_{n}-v_{n-1}\right|, v_{n}\right) .
$$

The restriction of $G$ to the subset

$$
Z=\left\{\left(v_{1}, \ldots, v_{n}\right) \in\left(\mathbb{R}^{d}\right)^{n-1}: v_{1} \neq 0 \text { and } v_{j+1} \neq v_{j} \text { for } j=1, \ldots, n-1\right\}
$$

is smooth. One concludes analogously as in the Proof of Lemma 1.5.4 that every element $\left(l_{1}, \ldots, l_{n}, v_{n}\right) \in \mathbb{R}_{>0}^{n-1} \times \mathbb{R}^{d}$, so that the length vector $\left(l_{1}, \ldots, l_{n},\left|v_{n-1}\right|\right)$ is generic, is a regular value of $\left.G\right|_{Z}$. Moreover, there are diffeomorphisms

$$
G^{-1}(\ell, \varepsilon e) \simeq C_{d}(\ell, \varepsilon)
$$

and

$$
G^{-1}(\ell, 0) \simeq E_{d}(\ell)
$$

If $0<\varepsilon<[\ell]$, then $G$ has no critical values on the interval in $\mathbb{R}^{n} \times \mathbb{R}^{d}$ connecting the two points $(\ell, 0)$ and $(\ell, \varepsilon e)$. Thus in this case there are diffeomorphisms

$$
C_{d}(\ell, \varepsilon) \simeq G^{-1}(\ell, \varepsilon e) \simeq G^{-1}(\ell, 0) \simeq E_{d}(\ell) .
$$

## A. 2 Cohomology of Spaces of polygonal Chains

In light of the second part of Proposition A.1.1, a possible analogue of Walker's Conjecture for the spaces $C_{d}(\ell)$ is the question whether for generic $\ell$ the graded isomorphism type of the cohomology ring $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ determines the chamber of
$\ell$ up to a permutation $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ with $\sigma(n)=n$. In [13], it was shown that the answer to this question is positive if one only considers length vectors that are dominated, i.e. so that $l_{n}$ is a maximal entry of $\ell$. We now show that if $d>3$, then the answer is negative in general, both for cohomology with coefficients in $\mathbf{Z}_{2}$ as well as for integral cohomology.

Let $n>3$. Suppose that $\ell$ is an ordered length vector with $a_{n-3}(\ell)=1$ (see Proposition 1.6.6) and that $\ell^{\prime}$ is obtained from $\ell$ by interchanging the entries $l_{n-3}$ and $l_{n}$. Explicitly, $\ell$ and $\ell^{\prime}$ can be chosen as follows. Let $0<\varepsilon<1 /(n-3)$. One defines $\ell$ and $\ell^{\prime}$ to be the length vectors with entries

$$
\begin{equation*}
l_{j}=\varepsilon \text { for } j \notin\{n-2, n-1, n\}, l_{n-2}=l_{n-1}=l_{n}=1 \tag{A.1}
\end{equation*}
$$

and

$$
\begin{equation*}
l_{j}^{\prime}=\varepsilon \text { for } j \notin\{n-3, n-2, n-1\}, l_{n-3}^{\prime}=l_{n-2}^{\prime}=l_{n-1}^{\prime}=1 . \tag{A.2}
\end{equation*}
$$

Note that $\ell$ is dominated while $\ell^{\prime}$ is not.

Proposition A.2.1. Let $n>3$ and let $\ell$ and $\ell^{\prime}$ be the length vectors given by A.1) and (A.2). There are diffeomorphisms

$$
C_{d}(\ell) \simeq\left(S^{d-1}\right)^{n-3} \times S^{d-2}
$$

and

$$
C_{d}\left(\ell^{\prime}\right) \simeq\left(S^{d-1}\right)^{n-4} \times T^{1} S^{d-1} .
$$

Proof. The first diffeomorphism follows from $C_{d}(1,1,1) \simeq S^{d-2}$ by successive application of the third part of Proposition A.1.1. The second diffeomorphism follows by combining the second part of Proposition A.1.2 with Proposition 1.6.6.

Corollary A.2.2. Let $d>3$. If $\ell$ and $\ell^{\prime}$ are as in A.1) and A.2, then the graded cohomology rings $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ and $H^{*}\left(C_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}_{2}\right)$ are isomorphic. If, in addition, $d$ is even, then the graded cohomology rings $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}\right)$ and $H^{*}\left(C_{d}\left(\ell^{\prime}\right) ; \mathbf{Z}\right)$ are isomorphic as well. However, there is no permutation $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ so that $\sigma(n)=n$ and the length vectors $\sigma(\ell)$ and $\ell^{\prime}$ lie in the same chamber.

Proof. In the case $d>3$ the ring $H^{*}\left(T^{1} S^{d-1} ; \mathbf{Z}_{2}\right)$ is uniquely determined by Poincaré duality and the fact that the non-vanishing groups $H^{p}\left(T^{1} S^{d-1} ; \mathbf{Z}_{2}\right)$ lie in dimensions $p=0, p=d-2, p=d-1$ and $p=2(d-1)-1$ and are all isomorphic to $\mathbf{Z}_{2}$ (see Example 3.2.5). The first assertion follows using Proposition A.2.1 and the Künneth theorem for cohomology. The second assertion follows analogously. The last claim of the Corollary follows from the fact that $\ell$ admits a long two-element subset $J \subset\{1, \ldots, n\}$ with $n \in J$ while $\ell^{\prime}$ does not.

In [13], the subring $H^{(d-1) *}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right) \subset H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ was computed in the case where the length vector $\ell$ is dominated. One can use similar arguments as were employed in the proof of Theorem 5.1.1 to extend the computation to the general case:

Proposition A.2.3. Let $\ell$ be a (not necessarily dominated) length vector and let $d>2$. Let $m \in\{1, \ldots, n\}$ be the index of any maximal entry of $\ell$. There is an isomorphism of graded rings

$$
H^{(d-1) *}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq \Lambda_{d}\left(Z_{1}, \ldots, Z_{\hat{m}}, \ldots Z_{n}\right) / I
$$

where $\Lambda_{d}\left(Z_{1}, \ldots, Z_{\hat{m}}, \ldots Z_{n}\right)$ is the exterior algebra on generators $Z_{1}, \ldots, Z_{n}$ of degree $d-1$ and $I$ is the ideal generated by all the monomials $Z^{J}=Z_{j_{1}} \cdots Z_{j_{k}}$ so that $J=\left\{j_{1}, \ldots, j_{k}\right\} \subset\{1, \ldots, \hat{m}, \ldots, n\}$ and the set $J \cup\{m\}$ is long with respect to $\ell$.

In the case where $\ell$ is dominated, $m=n$ and Proposition A.2.3 recovers the result of the computation in Section 3 of [13].

If $d>3$ and $\ell$ is generic, then the cohomology ring $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ can be recovered from the result of Proposition A.2.3 and Poincaré duality:

Proposition A.2.4. Let $\ell$ be a generic length vector and let $m \in\{1, \ldots, n\}$ be the index of any maximal entry of $\ell$. Assume that $d>3$. The cohomology $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ is additively generated by classes

$$
Z^{J} \in H^{(d-1)|J|}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right), Y^{K} \in H^{(d-1)(n-2-|K|)-1}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right),
$$

so that $J, K \subset\{1, \ldots, \hat{m}, \ldots, n\}$ and the sets $J \cup\{m\}$ and $K \cup\{m\}$ are short with respect to $\ell$. The product structure is given by

$$
\begin{gathered}
Z^{J} Z^{K}= \begin{cases}Z^{J \cup K} & \text { if } J \cap K=\emptyset \text { and } J \cup K \cup\{m\} \text { is short w.r.t. } \ell, \\
0 & \text { if } J \cap K \neq \emptyset \text { or } J \cup K \cup\{m\} \text { is long w.r.t. } \ell,\end{cases} \\
Z^{J} Y^{K}= \begin{cases}Y^{K-J} & \text { if } J \subset K, \\
0 & \text { if } J \nsubseteq K\end{cases}
\end{gathered}
$$

and

$$
Y^{J} Y^{K}=0 \text { for all } J, K
$$

Proof of Proposition A.2.4. The non-vanishing groups $H^{p}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ lie in dimensions

$$
p=(d-1) k, 0 \leq k \leq n-3 \text { and } p=(d-1) k-1,1 \leq k \leq n-2 .
$$

By Proposition A.2.3, an additive basis of the group $H^{(d-1) k}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ is given by classes $Z^{J}$ so that $J \subset\{1, \ldots, \hat{m}, \ldots, n\},|J|=k$ and the set $J \cup\{m\}$ is short with respect to $\ell$. There are isomorphisms

$$
\begin{gather*}
H^{(d-1)(n-2-|J|)-1}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq H_{(d-1)|J|}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)  \tag{A.3}\\
\simeq \operatorname{Hom}\left(H^{(d-1)|J|}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right), \mathbf{Z}_{2}\right) \tag{A.4}
\end{gather*}
$$

where the first isomorphism is given by Poincaré duality and the second isomorphism follows from the universal coefficient theorem. We define

$$
Y^{J} \in H^{(d-1)(n-2-|J|)-1}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)
$$

to be the elements of a dual basis under the identifications of A.3) and A.4 to the basis of $H^{(d-1)|J|}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ given by the classes $Z^{J}$. Thus the classes $Y^{J}$, where $|J|=k, m \notin J$ and $J \cup\{m\}$ is short with respect to $\ell$, form a basis of $H^{(d-1)(n-2-k)-1}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$. In particular, $Y^{\emptyset}$ is the generator of the group $H^{(d-1)(n-2)-1}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$.

It remains to show that products of classes $Z^{J}, Y^{K}$ can be expressed as in the
claim of the proposition. In the case of products of the form $Z^{J} Z^{K}$, this follows from Proposition A.2.3. Since for all $I, J, K$ with $|I|+|J|=|K|$,

$$
Z^{I}\left(Z^{J} Y^{K}\right)=Z^{I \cup J} Y^{K}=\left\{\begin{array}{cl}
{\left[C_{d}(l)\right]} & \text { if } I \cup J=K,  \tag{A.5}\\
0 & \text { if } I \cup J \neq K,
\end{array}\right.
$$

we find that the product $Z^{J} Y^{K}$ vanishes if $J \nsubseteq K$. In the case where $J \subset K$, it follows from A.5) and the definition of the classes $Y^{J}$ that $Z^{J} Y^{K}=Y^{K-J}$. Finally, if $d>3$, then products of the form $Y^{J} Y^{K}$ vanish for dimensional reasons.

Using the diffeomorphism $E_{d}(\ell) \simeq C_{d}(\ell, \varepsilon)$ established in Proposition A.1.2, one obtains as a special case of Proposition A.2.4 a computation of the cohomology ring $H^{*}\left(E_{d}(\ell) ; \mathbf{Z}_{2}\right)$ for $d>3$ and generic $\ell$.

In the case $d=2, C_{d}(\ell)$ coincides with the space $M_{\ell}$ of planar polygons, viewed up to all orientation-preserving Euclidean isometries. In particular, the homeomorphism type of the space $C_{2}(\ell)$ is invariant under arbitrary permutations of the entries of $\ell$. Together with the explicit description given in Proposition A.2.4 of the cohomology ring $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ for $d>3$, one concludes:

Corollary A.2.5. Let $\ell$ be a generic length vector. If $d \neq 3$, then for every permutation $\sigma:\{1, \ldots, n\} \rightarrow\{1, \ldots, n\}$ the graded cohomology rings $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ and $H^{*}\left(C_{d}(\sigma(\ell)) ; \mathbf{Z}_{2}\right)$ are isomorphic. Here $\sigma(\ell)$ denotes the length vector obtained from $\ell$ by permuting the entries by $\sigma$.

Note that the permutation $\sigma$ in Corollary A.2.5 may not fix the index $n$. Recall that $C_{d}(\ell)$ is the space of polygons up to translations, so that the direction of one of the edges in $d$-space is fixed. The Corollary means that in the case of $d \neq 3$, the isomorphism type of the ring $H^{*}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ is independent of the choice of the edge whose direction is fixed.

## A. 3 Proof of Proposition A.2.3

As noted above, it suffices to consider the case where the length vector $\ell$ is nondominated, i.e. when a maximal entry of $\ell$ has index $m \in\{1, \ldots, n-1\}$.

We recall that the space $C_{d}(\ell)$ is the intersection of $E_{d}(\ell) \subset W=\left(S^{d-1}\right)^{n}$ with the subspace $W^{\prime}=\left(S^{d-1}\right)^{n-1} \times\{-e\} \subset W$. Denote as in Section 3.5 for a subset $J \subset\{1, \ldots, n\}$ by $W_{J} \subset W$ the submanifold

$$
W_{J}=\left\{\left(u_{1}, \ldots, u_{n}\right) \in W: u_{i}=u_{j} \text { for } i, j \in J\right\} .
$$

Let $W_{J}^{\prime}$ be the intersection $W_{J}^{\prime}=W_{J} \cap W^{\prime}$. We note that if $n \in J$, then the submanifold $W_{J}^{\prime}$ is given by

$$
\begin{equation*}
\left\{\left(u_{1}, \ldots, u_{n-1}\right) \in\left(S^{d-1}\right)^{n-1}: u_{j}=-e \text { for } j \in J\right\} \tag{A.6}
\end{equation*}
$$

On the other hand, if $n \notin J$, then $W_{J}^{\prime}$ is given by

$$
\begin{equation*}
\left\{\left(u_{1}, \ldots, u_{n-1}\right) \in\left(S^{d-1}\right)^{n-1}: u_{i}=u_{j} \text { for } i, j \in J\right\} \tag{A.7}
\end{equation*}
$$

Comparing (A.6) and (A.7) with equations (3.10) and (3.11) in Section 3.5 and applying Lemma 3.5.3, we find that a basis of $H_{*}\left(W^{\prime} ; \mathbf{Z}_{2}\right)$ is given by the classes $\left[W_{J}^{\prime}\right]$, so that $J \subset\{1, \ldots, n\}$ is a subset with $m \in J$ (we recall that $m \in\{1, \ldots, n-1\}$ is the index of a maximal entry of $\ell$ ).

Lemma A.3.1. Let $\ell$ be a (not necessarily dominated) length vector. The image of the homomorphism

$$
j_{k}: H_{(d-1) k}\left(W^{\prime}-C_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow H_{(d-1) k}\left(W^{\prime} ; \mathbf{Z}_{2}\right)
$$

induced by inclusion is generated by all the classes $\left[W_{J}^{\prime}\right]$, so that $J \subset\{1, \ldots, n\}$ is a subset of cardinality $|J|=n-k$ which is long with respect to $\ell$ and contains the index $m$.

We now prove Proposition A.2.4 assuming Lemma A.3.1. For $j=1, \ldots, n-1$, denote by $\pi_{j}: W^{\prime} \rightarrow S^{d-1}$ the projection to the $j$ th factor. Let $X_{j} \in H^{d-1}\left(W^{\prime} ; \mathbf{Z}_{2}\right)$ be the pull-back $X_{j}=\pi_{j}^{*}\left(\left[S^{d-1}\right]\right)$ of the generator $\left[S^{d-1}\right] \in H^{d-1}\left(S^{d-1} ; \mathbf{Z}_{2}\right)$. It follows from
A.6) and A.7) that the Poincaré dual of the class $\left[W_{J}\right] \in H_{(d-1)(n-|J|)}\left(W^{\prime} ; \mathbf{Z}_{2}\right)$ may be expressed as follows:

$$
P D\left(\left[W_{J}\right]\right)= \begin{cases}X^{J-\{n\}} & \text { if } n \in J  \tag{A.8}\\ \sum_{j \in J} X^{J-j} & \text { if } n \notin J\end{cases}
$$

Here for as subset $J=\left\{j_{1}, \ldots, j_{k}\right\} \subset\{1, \ldots, n\}, X^{J}$ denotes the monomial $X^{J}=$ $X_{j_{1}} \cdots X_{j_{k}}$.

Arguing as in the proof of Proposition 5.1.2 in Section 5.3, the homomorphism $H^{(d-1) *}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow H^{(d-1) *}\left(W^{\prime} ; \mathbf{Z}_{2}\right)$ induced by inclusion is surjective and its kernel $I \subset H^{(d-1) *}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ is the ideal generated by the Poincaré duals of the elements of the image of $j_{*}: H_{(d-1) *}\left(W^{\prime}-C_{d}(\ell) ; \mathbf{Z}_{2}\right) \rightarrow H_{(d-1) *}\left(W^{\prime} ; \mathbf{Z}_{2}\right)$. Using A.8), it follows that

$$
H^{(d-1) *}\left(C_{d}(\ell) ; \mathbf{Z}_{2}\right) \simeq \Lambda_{d}\left(X_{1}, \ldots, X_{n-1}\right) / I
$$

where $I \subset \Lambda_{d}\left(X_{1}, \ldots, X_{n-1}\right)$ is the ideal generated by all the monomials $X^{K}$, so that $K \subset\{1, \ldots, n-1\}, m \in K$ and the set $K \cup\{n\}$ is long with respect to $\ell$ as well as all the sums $\sum_{j \in J} X^{J-j}$, so that $J \subset\{1, \ldots, n-1\}, m \in J$ and $J$ is long with respect to $\ell$.

Consider the following change of variables: we denote

$$
Z_{j}=X_{j}+X_{m} \text { for } j \neq m, n \text { and } Z_{n}=X_{m} .
$$

Then for every subset $J \subset\{1, \ldots, n-1\}$ with $m \in J$,

$$
X^{J}=Z^{J-\{m\} \cup\{n\}} \text { and } \sum_{j \in J} X^{J-\{j\}}=Z^{J-\{m\}} .
$$

It follows that $I$ corresponds to the ideal in $\Lambda_{d}\left(Z_{1}, \ldots, Z_{\hat{m}}, \ldots, Z_{n}\right)$ generated by all the monomials $Z^{J}$, so that $J \subset\{1, \ldots, \hat{m}, \ldots n\}$ and the set $J \cup\{m\}$ is long with respect to $\ell$. This completes the proof of Proposition A.2.4.

The proof of Lemma A.3.1 uses the explicit description of the homology $H_{*}\left(W^{\prime}-\right.$ $\left.C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ which was obtained in [13]. Namely, it was shown in Lemma 1.3 of [13]
that the homology $H_{*}\left(W^{\prime}-C_{d}(\ell) ; \mathbf{Z}_{2}\right)$ of the complement of $C_{d}(\ell)$ in $W^{\prime}$ has a basis consisting of all the classes $\left[W_{J}^{\prime}\right]$, so that the subset $J \subset\{1, \ldots, n\}$ is long with respect to $\ell$. Similarly as in the proof of Lemma 3.5.5 in Section 3.5, we consider direct sum decompositions

$$
H_{(d-1) k}\left(W^{\prime}-C_{d}(\ell) ; \mathbf{Z}_{2}\right)=A_{k} \oplus A_{k}^{\prime} \oplus B_{k} \oplus B_{k}^{\prime}
$$

and

$$
H_{(d-1) k}\left(W^{\prime} ; \mathbf{Z}_{2}\right)=A_{k} \oplus B_{k} \oplus C_{k} \oplus D_{k}
$$

where

- $A_{k}\left(\right.$ respectively $\left.A_{k}^{\prime}\right)$ is generated by the classes $\left[W_{J}^{\prime}\right]$ so that $|J|=n-k$, $n \notin J, J$ is long with respect to $\ell$ and $m \in J$ (respectively $m \notin J$ ).
- $B_{k}$ (respectively $B_{k}^{\prime}$ ) is generated by the classes $\left[W_{J}^{\prime}\right]$ so that $|J|=n-k$, $n \in J, J$ is long with respect to $\ell$ and $m \in J$ (respectively $m \notin J$ ).

Moreover,

- $C_{k}$ is generated by the classes $\left[W_{J}^{\prime}\right]$ so that $|J|=n-k, m \in J, J$ is short or median with respect to $\ell$ and $n \notin J$.
- $D_{k}$ is generated by the classes $\left[W_{J}^{\prime}\right]$ so that $|J|=n-k, m \in J, J$ is short or median with respect to $\ell$ and $n \in J$.

Using the formula

$$
\left[W_{J}^{\prime}\right] \cdot\left[W_{K}^{\prime}\right]= \begin{cases}1 & \text { if }|J \cap K|=1 \\ 0 & \text { if }|J \cap K|>1\end{cases}
$$

for the intersection number of any two classes $\left[W_{J}^{\prime}\right],\left[W_{K}^{\prime}\right]$ with $|J|+|K|=n+1$ and repeating the arguments in the proof of Lemma 3.5.5, one concludes that the image of the inclusion homomorphism $j_{k}$ is given by $A_{k} \oplus B_{k}$. This completes the proof of Lemma A.3.1.
