#### Abstract

We show that the adjunction counits of a Fourier-Mukai transform $\Phi: D\left(X_{1}\right) \rightarrow D\left(X_{2}\right)$ arise from maps of the kernels of the corresponding Fourier-Mukai transforms. In a very general setting of proper separable schemes of finite type over a field we write down these maps of kernels explicitly - facilitating the computation of the twist (the cone of an adjunction counit) of $\Phi$. We also give another description of these maps, better suited to computing cones if the kernel of $\Phi$ is a pushforward from a closed subscheme $Z \subset X_{1} \times X_{2}$. Moreover, we show that we can replace the condition of properness of the ambient spaces $X_{1}$ and $X_{2}$ by that of $Z$ being proper over them and still have this description apply as is. This can be used, for instance, to compute spherical twists on non-proper varieties directly and in full generality. (C) 2012 Elsevier Inc. All rights reserved.

Keywords: Fourier-Mukai transforms; Derived categories; Algebraic geometry; Spherical twists; Adjunction; Künneth map

## 1. Introduction

The bounded derived category $D(X)$ of coherent sheaves on a variety $X$ had long been recognized as a crucial invariant of $X$ which holds a wealth of information about its geometry. In order to work conveniently with functors between the derived categories of two varieties the language of Fourier-Mukai transforms was developed by Mukai, Bondal and Orlov, Bridgeland and many others. In brief, we can define a functor $D\left(X_{1}\right) \rightarrow D\left(X_{2}\right)$ by specifying an object in the derived category of $D\left(X_{1} \times X_{2}\right)$. A morphism between such defining objects induces a natural transformation between the functors. In this paper we write down the adjunction

[^0]counit of a general Fourier-Mukai transform in this language - as morphisms of defining objects.

Let $X_{1}$ and $X_{2}$ be a pair of smooth projective varieties. We have the following commutative diagram:

Let $E \in D\left(X_{1} \times X_{2}\right)$. The Fourier-Mukai transform from $X_{1}$ to $X_{2}$ with kernel $E$ is the functor

$$
\begin{equation*}
\Phi_{E}(-)=\pi_{2 *}\left(E \otimes \pi_{1}^{*}(-)\right) . \tag{1.2}
\end{equation*}
$$

Here and throughout the paper all the functors are derived unless mentioned otherwise. It is well-known (e.g. [4], Lemma 1.2) that the left adjoint of $\Phi_{E}$ is the Fourier-Mukai transform from $D\left(X_{2}\right)$ to $D\left(X_{1}\right)$ with kernel $E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)$ where $\pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)=\pi_{2}^{*}\left(\omega_{X_{2}}\right)\left[\operatorname{dim} X_{2}\right]$. Denote this adjoint by $\Phi_{E}^{l a d j}$. A composition of Fourier-Mukai transforms is again a Fourier-Mukai transform ([15], Prop. 1.3). In particular, $\Phi_{E}^{\text {ladj }} \Phi_{E}$ is the Fourier-Mukai transform $D\left(X_{1}\right) \rightarrow$ $D\left(X_{1}\right)$ with kernel

$$
\begin{equation*}
Q=\pi_{13 *}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) . \tag{1.3}
\end{equation*}
$$

On the other hand, the identity functor Id is the Fourier-Mukai transform $D\left(X_{1}\right) \rightarrow D\left(X_{1}\right)$ with kernel $\mathcal{O}_{\Delta}=\Delta_{*} \mathcal{O}_{X_{1}}$ where $\Delta$ is the diagonal inclusion $X_{1} \hookrightarrow X_{1} \times X_{1}$.

Consider now the left adjunction counit

$$
\begin{equation*}
\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow \mathrm{Id} \tag{1.4}
\end{equation*}
$$

In general, morphisms between Fourier-Mukai kernels map neither injectively nor surjectively to natural transformations between the Fourier-Mukai transforms. Thus there is no a priori reason for (1.4) to come from some morphism $Q \rightarrow \mathcal{O}_{\Delta}$. In this paper we construct explicitly a natural choice of such morphism, working in a much greater generality of separated schemes of finite type over a field.

The principal application is to compute, and even define, spherical twists. These are an important class of auto-equivalences of the derived category $D(X)$ of a variety $X$. They are first examples of genuinely derived auto-equivalences, in a sense that they are neither shifts, nor come from auto-equivalences of the underlying abelian category $\operatorname{Coh} X$. In brief, a spherical twist is an auto-equivalence of $D(X)$ produced from a spherical object in $D(X)$ or, more generally, a spherical functor $D(Y) \rightarrow D(X)$. Spherical objects were introduced by Seidel and Thomas in [21] as mirror symmetry analogues of Lagrangian spheres on a symplectic manifold. Their defining properties ensure that the twist by a spherical object is an auto-equivalence of $D(X)$. This was generalized in [2] to exact functors between triangulated categories in such a way that Seidel-Thomas spherical objects are precisely the (Fourier-Mukai kernels of) spherical functors $D($ Spec $k) \rightarrow D(X)$, where $k$ is the base field.

Taking the twist of a functor is completely general and does not in itself rely on the fact that the functor is spherical. The ideal definition would be the following:
"Definition": Let $C_{1}$ and $C_{2}$ be triangulated categories. Let $S$ be an exact functor $C_{1} \rightarrow C_{2}$ which has a right (resp. left) adjoint $R$ (resp. L). The twist (resp. the dual co-twist) of $S$ is the functor $T_{S}: C_{2} \rightarrow C_{2}$ (resp. $F_{S}^{\prime}: C_{1} \rightarrow C_{1}$ ) which is the functorial cone of the adjunction counit $S R \rightarrow \mathrm{Id}$ (resp. $L S \rightarrow \mathrm{Id}$ ).

The problem with this definition is the well-known fact that cones in triangulated categories are not functorial. The cone of a morphism between two objects is uniquely defined (up to an isomorphism), but a cone of a morphism between two functors might not exist or might not be unique. This is usually fixed by restricting to a setting where the cone of a morphism of functors is well-defined, cf. [2], Section 1. One way is to consider only the functors which are Fourier-Mukai transforms and only the natural transformations which come from morphisms of Fourier-Mukai kernels. But then to define a twist of a Fourier-Mukai transform we need a natural choice of the morphism of Fourier-Mukai kernels underlying the corresponding adjunction counit, while to compute the twist we need an efficient way of computing the cone of this morphism. This paper addresses both of these issues.

The construction of the natural morphism of Fourier-Mukai kernels underlying the adjunction counit of a general Fourier-Mukai transform is carried out in Section 3. Thanks to the recent advances in Grothendieck duality machinery summarized in Section 2 we can work with separated schemes of finite type over a field and with derived categories $D_{q c}(-)$ of unbounded complexes with quasi-coherent cohomology. So let $X_{1}$ and $X_{2}$ be two separated schemes of finite type, $E$ a perfect object of $D\left(X_{1} \times X_{2}\right)$ and $\Phi_{E}$ the Fourier-Mukai transform $D\left(X_{1}\right) \rightarrow D\left(X_{2}\right)$ with kernel $E$. Let $X_{2}$ be proper, so that the left adjoint $\Phi_{E}^{\text {ladj }}$ of $\Phi_{E}$ is again a Fourier-Mukai transform. Then the left adjunction counit $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id is induced by the morphism $Q=\pi_{13 *}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \rightarrow \mathcal{O}_{\Delta}$ which roughly is the composition of the following:

$$
\begin{align*}
& \pi_{13 *}\left(\text { The adjunction unit Id } \rightarrow \Delta_{13 *} \Delta_{13}^{*} \text { for the diagonal } X_{1} \times X_{2} \xrightarrow{\Delta_{13}} X_{1} \times X_{2} \times X_{1}\right)  \tag{1.5}\\
& \Delta_{*} \pi_{1 *}\left(\text { The evaluation map } E \otimes E^{\vee} \rightarrow \mathcal{O}_{X_{1} \times X_{2}} \text { on } X_{1} \times X_{2}\right)  \tag{1.6}\\
& \Delta_{*}\left(\text { The adjunction counit } \pi_{1 *} \pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right) \rightarrow \mathcal{O}_{X_{1}}\right) . \tag{1.7}
\end{align*}
$$

For the precise formulas see Theorem 3.1. When $X_{1}$ is also proper $\Phi_{E}, \Phi_{E}^{\text {ladj }}$ and (1.5)-(1.7) restrict to the full subcategories of $D_{q c}(-)$ consisting of bounded complexes with coherent cohomologies. If $X_{2}$ is smooth $\pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)=\pi_{2}^{*}\left(\omega_{X_{2}}\right)$ [dim $X_{2}$ ] as before. Theorem 3.2 give the analogous result for the right adjunction counit.

This allows us to define the twist and the dual co-twist of any Fourier-Mukai transform. Section 4 deals with the issue of computing them. Anyone trying to compute the cone of the decomposition (1.5)-(1.7) will find it ill-suited to the task if the support of $E$ has high codimension in $X_{1} \times X_{2}$. We give an example in Section 4.1 with $E$ the structure sheaf $\mathcal{O}_{Z}$ of a complete intersection subscheme $Z$ in $X_{1} \times X_{2}$ of codimension $d>0$ which satisfies certain transversality conditions. Then morphisms (1.5) and (1.6) both have huge cones with non-zero cohomologies in all degrees from $-d$ to 0 . However these two cones mostly annihilate each other and the cone of composition (1.5)-(1.6) is actually quite small. This suggests an alternative decomposition of (1.5)-(1.6) better suited to computing cones, cf. (4.4).

In the rest of Section 4 we make this into a general argument. The key idea is to take the decomposition (1.5)-(1.7) obtained in Section 3 and apply to it the base change for Künneth maps. If $E$ is a pushforward of an object from a closed subscheme $Z \stackrel{{ }^{I Z}}{\longrightarrow} X_{1} \times X_{2}$, then the evaluation map $E \otimes E^{\vee} \rightarrow \mathcal{O}_{X_{1} \times X_{2}}$ involves the derived self-intersection of $Z$ inside $X_{1} \times X_{2}$. In precise terms, it involves the Künneth map (see Section 4.3 for the definition) for the fiber square $\sigma_{\Delta}$ depicted on the left in (1.8):

Thus in (1.5)-(1.6) we first restrict fiber square $\sigma$ to the diagonal $X_{1} \times X_{2}$ in $X_{1} \times X_{2} \times X_{1}$ which turns it into $\sigma_{\Delta}$ and then we do the Künneth map on $\sigma_{\Delta}$. Given two subschemes, the cone of the Künneth map for the fiber square of their intersection reflects, roughly, how far this intersection is from transverse. In $\sigma_{\Delta}$ we have the self-intersection of $Z$ in $X_{1} \times X_{2}$ which is the opposite of transverse. This suggests first doing the Künneth map on $\sigma$, as the intersection of $Z \times X_{1}$ with $X_{1} \times Z$ in $X_{1} \times X_{2} \times X_{1}$ may be more transverse, and then restricting to the diagonal $Z$ in $Z^{\prime}$.

Write $\pi_{Z 1}$ for the composition $Z \stackrel{\iota_{Z}}{\longrightarrow} X_{1} \times X_{2} \xrightarrow{\pi_{1}} X_{1}$. In Proposition 4.4 we prove that Künneth maps commute with arbitrary base change. Then in Theorem 4.1 we show that the composition (1.5)-(1.7) is isomorphic to roughly the following (cf. Theorem 4.1 for precise formulas):

$$
\begin{align*}
& \pi_{13 *}(\text { The Künneth map for } \sigma)  \tag{1.9}\\
& \pi_{13 *}{ }^{\prime} Z^{\prime} *\left(\text { The adjunction unit } \operatorname{Id} \rightarrow \Delta_{*}^{\prime} \Delta^{\prime *} \text { for the diagonal } Z \xrightarrow{\Delta^{\prime}} Z^{\prime}\right)  \tag{1.10}\\
& \Delta_{*} \pi_{Z 1 *}(\text { The evaluation map for } E \text { on } Z)  \tag{1.11}\\
& \Delta_{*}\left(\text { The adjunction counit } \pi_{Z 1 *} \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right) \rightarrow \mathcal{O}_{X_{1}}\right) . \tag{1.12}
\end{align*}
$$

This is our preferred decomposition of morphism $Q \rightarrow \mathcal{O}_{\Delta}$. Theorem 4.2 gives the analogous statement for the right adjunction counit.

One advantage of decomposition (1.9)-(1.12) is that most of the morphisms in it can become isomorphisms under fairly reasonable assumptions on $E$ and $Z$. Indeed, while the Künneth map for square $\sigma_{\Delta}$ is never an isomorphism unless $Z$ is the whole of $X_{1} \times X_{2}$, the Künneth map for $\sigma$ is an isomorphism whenever the intersection of $Z \times X_{1}$ with $X_{1} \times Z$ in $X_{1} \times X_{2} \times X_{1}$ is transverse. The evaluation map for $E$ on $Z$ is an isomorphism whenever $E$ is a line bundle or any invertible object of $D(Z)$. The adjunction counit in (1.12) is an isomorphism whenever $Z \xrightarrow{\pi_{Z 1}} X_{1}$ is such that $\pi_{Z 1 *} \mathcal{O}_{Z}=\mathcal{O}_{X_{1}}$, e.g. $Z$ is a blowup of $X_{1}$ or a Fano fibration over it. This allows for a number of scenarios where the twist or the dual co-twist of $\Phi_{E}$ can be written down fairly easily, as we demonstrate in Corollary 4.5.

Another advantage of decomposition (1.9)-(1.12) is that it moves the action away from ambient spaces $X_{1} \times X_{2} \times X_{1}$ and $X_{1} \times X_{2}$ to their subschemes $Z^{\prime}$ and $Z$. This allows us to replace the assumption of $X_{2}$ being proper by the assumption of $Z$ being proper over $X_{1}$ and
$X_{2}$ (see Theorem 4.1). Something to be appreciated by those who want to do spherical twists on non-compact varieties, e.g. total spaces of cotangent bundles of projective varieties.

Finally, in Section 5 we give an example of an explicit computation using Theorem 4.1. We consider the naive derived category transform induced by a Mukai flop. This transform is not an equivalence - it was proved by Namikawa in [17] by direct comparison of Hom spaces. We demonstrate how its dual co-twist can be computed quickly and efficiently by our methods.

## 2. Preliminaries

Let $k$ be an algebraically closed field of characteristic 0 . The level of generality we choose to work at in the main body of this paper is that of separated schemes of finite type over $k$. These assumptions are necessary for the Grothendieck duality machinery which ensures that the direct image functor in the definition of a Fourier-Mukai transform has a right adjoint. Without them we cannot expect a general Fourier-Mukai transform to have a right and a left adjoint.

Some of the auxiliary results we prove along the way hold in a greater generality than the one above. We would like to think of these results as being of potential interest to others who find themselves in an unfortunate situation of having to show a complicated diagram of derived functors to commute. We try therefore to state these results in maximal generality they hold at.

By a ringed space we always mean a commutative ringed space. By a concentrated map of schemes we mean a map which is quasi-compact and quasi-separated. A scheme $X$ is said to be concentrated if it is concentrated over Spec $\mathbb{Z}$. If $Y$ is a concentrated scheme, then a map $X \rightarrow Y$ is concentrated if and only if $X$ is concentrated [6, Section 1.2].

We make frequent use of a notion of a perfect map of schemes $X \xrightarrow{f} Y$, cf. [8, Section 4]. For maps of finite type between noetherian schemes $f$ is perfect if and only if it is of finite Tor-dimension, i.e. the derived functor of $f^{*}$ is cohomologically bounded.

Given an adjoint pair of functors $(F, G)$, by the right adjoint with respect to $F$ of some natural transformation $F H_{1} \rightarrow H_{2}$, we mean the natural transformation $H_{1} \rightarrow G H_{2}$ induced by the adjunction. Similarly, by the left adjoint with respect to $G$ of some $H_{1} \rightarrow G H_{2}$ we mean the F $H_{1} \rightarrow H_{2}$ induced by the adjunction.

Throughout the paper we employ a variety of Greek letters to denote an assortment of natural maps which exist between compositions of standard derived functors. These are defined at length over the course of Sections 2.1-2.3, but for the convenience of our readers we have also compiled a brief index:

|  | the projection formula |  |
| :---: | :---: | :---: |
| $\alpha_{f}$ | $f_{*} A \otimes B \rightarrow f_{*}\left(A \otimes f^{*} B\right)$ | $(2.28)$ |

| $v_{A}$ | $\mathbf{R} \mathcal{H o m}(A \otimes B, C) \xrightarrow{\sim} \mathbf{R} \mathcal{H} \operatorname{om}(B, \mathbf{R} \mathcal{H} \operatorname{om}(A, C))$ | (2.8) |
| $\chi_{f}$ | $f^{\times} A \otimes f^{*} B \rightarrow f^{\times}(A \otimes B)$ | (2.32) |

### 2.1. Derived categories and derived functors

Let $X$ be a scheme or a ringed space. We denote by $D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)$ the unbounded derived category of the abelian category $\mathcal{O}_{X}-$ Mod. We denote by $D_{\mathrm{qc}}(X)$ (resp. $D(X)$ ) the full subcategory of $\mathcal{O}_{X}$-Mod consisting of complexes with quasi-coherent (resp. bounded and coherent) cohomology. We denote by $D_{\text {perf }}(X)$ the full subcategory of $D(X)$ consisting of the objects which are locally quasi-isomorphic to a bounded complex of free $\mathcal{O}_{X}$-modules of finite rank.

For a reference text on derived categories and derived functors we recommend [7], for the traditional approach, and [13], for a more modern approach. One should also mention the expositions in [10] and [19]. A key feature of the modern approach is that thanks to the results of [20] we can now work freely with unbounded complexes. The authors of this paper adhere to a general principle that wherever possible general results on derived functors and isomorphisms between them should first be proved in the setting of $D_{\mathrm{qc}}(-)$, and then shown to restrict to the usual setting of $D(-)$ where applicable.

All the functors in this paper are assumed to be derived, unless specifically mentioned otherwise. With two exceptions listed below we suppress all the usual R's and L's and use the same notation for the derived functor as for its abelian category counterpart. Below we summarize basic facts about the derived functors we make use of.

Let $X$ be a ringed space. The derived tensor product functor exists as a functor

$$
(-) \otimes(-): D\left(\mathcal{O}_{X}-\text { Mod }\right) \times D\left(\mathcal{O}_{X}-\text { Mod }\right) \rightarrow D\left(\mathcal{O}_{X}-\text { Mod }\right)
$$

and always restricts to a functor $D_{\mathrm{qc}}(X) \times D_{\mathrm{qc}}(X) \rightarrow D_{\mathrm{qc}}(X)$ [13, Section 2.5]. For $X$ a locally noetherian scheme and for $A \in D_{\text {perf }}(X)$ the functor $A \otimes$ - restricts to a functor $D(X) \rightarrow D(X)$ [7, Prop. II.4.3]. Similarly, for any $n \in \mathbb{Z}$ the derived tensor product functor in $n$ variables $(-) \otimes \cdots \otimes(-)$ exists as a functor from the product of $n$ copies of $D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)$ into $D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)$ [13, Section 2.5.9].

The derived functor of the functor $\operatorname{Hom}_{X}(-,-)$ of taking the global Hom space between two $\mathcal{O}_{X}$-modules exists as a functor

$$
\mathbf{R} \operatorname{Hom}_{X}(-,-): D\left(\mathcal{O}_{X} \text {-Mod }\right)^{\mathrm{opp}} \times D\left(\mathcal{O}_{X} \text {-Mod }\right) \rightarrow D\left(\Gamma\left(\mathcal{O}_{X}\right) \text {-Mod }\right),
$$

see [13, Section 2.4]. We make an exception and do not suppress ' $\mathbf{R}$ ' here in order to differentiate the object $\mathbf{R} \operatorname{Hom}_{X}(A, B)$ in $D\left(\Gamma\left(\mathcal{O}_{X}\right)\right.$-Mod) from the morphism space $\operatorname{Hom}_{D(X)}(A, B)$.

Similarly, the derived functor of the sheafified Hom functor $\mathcal{H o m}_{X}(-,-)$ exists as a functor

$$
\mathbf{R} \mathcal{H o m}_{X}(-,-): D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)^{\mathrm{opp}} \times D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)
$$

We do not suppress ' $\mathbf{R}$ ' here to emphasize the relation with $\mathbf{R} \operatorname{Hom}_{X}$. If $X$ is a locally noetherian scheme, then for any $A \in D(X)$ the functor $\mathbf{R} \mathcal{H o m}_{X}(A,-)$ restricts to a functor $D_{q c}^{+}(X) \rightarrow$ $D_{q c}(X)$ [7, Prop. II.3.3]. Here $D_{q c}^{+}(X)$ is the subcategory of $D_{q c}(X)$ consisting of complexes with bounded below cohomology. If $X$ is a noetherian scheme and $A$ is perfect the functor $\mathbf{R} \operatorname{Hom}_{X}(A,-)$ restricts to a functor $D_{\mathrm{qc}}(X) \rightarrow D_{\mathrm{qc}}(X)$ and then to a functor $D(X) \rightarrow D(X)$ [3, Lemma 1.4.6].

Let now $Y$ be another ringed space, and let $f: X \rightarrow Y$ be a map of ringed spaces.
The derived direct image functor exists as a functor

$$
f_{*}(-): D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right),
$$

cf. [13, Section 3.1]. When $f$ is a concentrated map of schemes $f_{*}$ restricts to a functor $D_{\mathrm{qc}}(X) \rightarrow D_{\mathrm{qc}}(Y)$ [13, Prop. 3.9.2]. If $X$ and $Y$ are noetherian and $f$ is proper ${ }^{1}$ then $f_{*}$ restricts to a functor $D(X) \rightarrow D(Y)$ [8, Théorème 2.2.1].

The derived inverse image functor exists as a functor

$$
f^{*}(-): D\left(\mathcal{O}_{Y} \text {-Mod }\right) \rightarrow D\left(\mathcal{O}_{X} \text {-Mod }\right)
$$

cf. [13, Section 3.1]. When $f$ is a concentrated map of schemes $f^{*}$ restricts to a functor $D_{\mathrm{qc}}(Y) \rightarrow D_{\mathrm{qc}}(X)$ [13, Prop. 3.9.1]. If $X$ and $Y$ are locally noetherian and $f$ is perfect, then $f^{*}$ restricts to a functor $D(Y) \rightarrow D(X)$ [7, Prop. II4.4].

### 2.2. Adjunctions and dualities for derived functors

Let $X$ be a ringed space. For any $A \in D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)$ the functor

$$
A \otimes(-): D\left(\mathcal{O}_{X} \text {-Mod }\right) \rightarrow D\left(\mathcal{O}_{X} \text {-Mod }\right)
$$

is left adjoint to functor

$$
\mathbf{R} \mathcal{H o m}_{X}(A,-): D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{X}-\mathbf{M o d}\right),
$$

cf. [13, Prop. 2.6.1].
For any $A \in D\left(\mathcal{O}_{X}\right.$-Mod) denote by $A^{\vee}$ the object $\mathbf{R} \operatorname{Hom}_{X}\left(A, \mathcal{O}_{X}\right) \in D\left(\mathcal{O}_{X}\right.$-Mod). There is a natural morphism $A \rightarrow A^{\vee \vee}$ which is an isomorphism for any $A \in D_{\text {perf }}(X)$ [9, Prop. 7.2]. So $(-)^{\vee}$ restricts to a self-inverse category equivalence $D_{\text {perf }}(X) \rightarrow D_{\text {perf }}(X)^{o p p}$ giving us the duality functor for perfect complexes.

For any $A \in D_{\text {perf }}(X)$ there is a canonical isomorphism $A^{\vee} \otimes(-) \simeq \mathbf{R} \mathcal{H o m}_{X}(A,-)$, see Section 2.3(3), so

$$
A \otimes(-): D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)
$$

is both the left and the right adjoint of functor

$$
A^{\vee} \otimes(-): D\left(\mathcal{O}_{X}-\text { Mod }\right) \rightarrow D\left(\mathcal{O}_{X}-\text { Mod }\right)
$$

[^1]Let now $Y$ be another ringed space and let $f: X \rightarrow Y$ be a map of ringed spaces. Then functor

$$
f^{*}(-): D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)
$$

is left adjoint to functor

$$
f_{*}(-): D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right),
$$

cf. [13, Prop. 3.2.1].
Suppose now that $X$ and $Y$ are concentrated schemes and let $f: X \rightarrow Y$ be a scheme map. Then the functor

$$
f_{*}(-): D_{\mathrm{qc}}(X) \rightarrow D_{\mathrm{qc}}(Y)
$$

has a right adjoint which we denote as

$$
f^{\times}(-): D_{\mathrm{qc}}(Y) \rightarrow D_{q c}(X),
$$

cf. [13, Theorem 4.1] or [18, Section 4].
To state the rest of the Grothendieck duality results in their full presently known generality we would have to introduce a number of notions (pseudo-coherence, quasi-properness, etc.) which are only meaningfully different from well-established ones in non-noetherian context. Since the main bulk of this paper deals with schemes of finite type over a field, we prefer to state these results for noetherian schemes only and refer the reader to [13, Section 4] for a more general story.

So let $X$ and $Y$ be noetherian schemes and let $f: X \rightarrow Y$ be a separated scheme map of finite type. Adjunction $\left(f_{*}, f^{\times}\right)$induces a natural morphism $\delta_{f}: f_{*} \mathbf{R} \mathcal{H o m}_{X}\left(A, f^{\times} B\right) \rightarrow$ $\mathbf{R} \mathcal{H o m}_{Y}\left(f_{*} A, B\right)$, see Section 2.3(10), often referred to as the sheafified Grothendieck duality morphism. For $\delta_{f}$ to be an isomorphism we need $f^{\times}$to commute with restriction to open sets of $Y$ [13, Section 4.6]. When $f$ is proper $f^{\times}$commutes with Tor-independent base change for all objects in $D_{q c}^{+}(Y)$ and so $\delta_{f}$ is an isomorphism for all $A \in D_{q c}(X)$ and $B \in D_{q c}^{+}(Y)$ [13, Section 4.4]. If $f$ is also perfect, then $f^{\times}$commutes with Tor-independent base change for all of $D_{q c}(Y)$ and so $\delta_{f}$ is an isomorphism for all $A, B \in D_{q c}(Y)$ [13, Theorem 4.7.4]. Moreover, the natural map $\chi_{f}: f^{\times}(A) \otimes f^{*}(B) \xrightarrow{\sim} f^{\times}(A \otimes B)$, cf. Section 2.3(11), is an isomorphism for all $A, B \in D_{q c}(X)[18$, Section 5].

By a result of Nagata any separated map of finite type between noetherian schemes decomposes as an open immersion followed by a proper map ([16], or [23] for a more modern exposition). So to make $(-)^{\times}$commute with flat base change we can try and modify its behavior over open immersions. Indeed, there is a unique way to paste $(-)^{\times}$over proper maps with $(-)^{*}$ over étale maps in a way compatible with étale base change of $(-)^{\times}$(see [13], Theorem 4.8.1 for more detail). The result is the pseudo-functor $(-)^{!}$, Deligne's twisted inverse image pseudofunctor, which associates to any finite-type separated map $f: X \rightarrow Y$ of noetherian schemes a functor $f^{!}: D_{q c}^{+}(Y) \rightarrow D_{q c}^{+}(X)$ with a number of nice properties:
(1) $f^{!}=\left.f^{\times}\right|_{D_{q c}^{+}}$when $f$ is proper and $f^{!}=\left.f^{*}\right|_{D_{q c}^{+}}$when $f$ is étale.
(2) For any $f$ functor $f^{!}$commutes with Tor-independent base change [13, Theorem 4.8.3].
(3) For perfect $f$ functor $f$ ! restricts to a functor $D(Y) \rightarrow D(X)$ [3, Remark 2.1.5].
(4) There exists, as explained in [13, Section 4.9.1], for all $A \in D_{q c}^{+}(X)$ a natural morphism

$$
\begin{equation*}
f^{!}\left(\mathcal{O}_{Y}\right) \otimes f^{*}(A) \rightarrow f^{!}(A) \tag{2.1}
\end{equation*}
$$

If $f$ is perfect then (2.1) is an isomorphism [13, Theorem 4.9.4] and the morphism

$$
\begin{equation*}
f^{*}(A) \rightarrow \mathbf{R} \mathcal{H o m}_{X}\left(f^{!}\left(\mathcal{O}_{Y}\right), f^{!}(A)\right) \tag{2.2}
\end{equation*}
$$

right adjoint to (2.1) with respect to $f^{!}\left(\mathcal{O}_{Y}\right) \otimes(-)$ is also an isomorphism [3, Lemma 2.1.10].
(5) If $f$ is a regular immersion of codimension $n$, then $f^{!}\left(\mathcal{O}_{Y}\right)=\omega_{X / Y}[-n]$ where $\omega_{X / Y}$ is the top wedge power of the normal bundle $\mathcal{N}_{X / Y}$ [7, Cor. III.7.3].
(6) If $f$ is smooth of relative dimension $n$, then $f^{!}\left(\mathcal{O}_{Y}\right)=\omega_{X / Y}[n]$ where $\omega_{X / Y}$ is the top wedge power of the sheaf $\Omega_{X / Y}^{1}$ of relative differentials [22, Theorem 3].

When $f$ is both perfect and proper, then $f^{!}=\left.f^{\times}\right|_{D_{q c}^{+}}$and all the above properties of $f^{!}$apply to the whole of $f^{\times}: D_{q c} \rightarrow D_{q c}$. We do not therefore distinguish between $f^{!}$and $f^{\times}$when $f$ is perfect and proper.

If $f$ is proper the RHS of (2.2), as a functor in $A$, has left adjoint $f_{*}\left(f^{!} \mathcal{O}_{Y} \otimes(-)\right)$. If $f$ is also perfect we denote this functor by $f_{!}$and the fact that (2.2) is an isomorphism implies immediately that $f_{!}: D_{q c}(X) \rightarrow D_{q c}(Y)$ is the left adjoint of $f^{*}: D_{q c}(Y) \rightarrow D_{q c}(X)$ and the adjunction counit $f!f^{*} \rightarrow$ Id is the composition

$$
f_{!} f^{*}(-)=f_{*}\left(f^{!}\left(\mathcal{O}_{Y}\right) \otimes f^{*}(-)\right) \xrightarrow{(2.1)} f_{*} f^{!}(-) \xrightarrow{\text { adj. counit }} \text { Id . }
$$

Finally, let $X$ be a separated scheme of finite type over a field $k$ and let $\pi_{k}: X \rightarrow k$ be the structure morphism. The functor $\mathbf{R} \mathcal{H o m}{ }_{X}\left(-, \pi_{k}^{\prime} k\right)$ restricts to a self-inverse category equivalence $D(X) \rightarrow D(X)^{o p p}$, the global ${ }^{2}$ Grothendieck duality functor $D_{X / k}$. For any separated finite-type map $f: X \rightarrow Y$ between two schemes of finite-type over $k$, the duality $D_{\bullet} / k$ interchanges $f^{*}$ and $f^{!}$[13, Prop. 4.10.1]. For proper $f$ the dual of $f_{*}$ under $D_{\bullet / k}$ is $f_{*}$ itself - this is precisely the sheafified Grothendieck duality isomorphism.

### 2.3. Standard relations between derived functors

There exists a number of well-known morphisms and isomorphisms between compositions of the derived functors listed in Sections 2.1 and 2.2. Here we compile for the convenience of the reader a list of such elementary relations employed throughout this paper.

For a number of these morphisms of derived functors we say below that they are compatible with the corresponding natural morphisms for sheaves. For full detail on this the reader should consult the reference we quote for each result, but roughly we mean the following. A natural transformation of compositions of derived functors

$$
\begin{equation*}
\mathbf{R} f_{1} \circ \cdots \circ \mathbf{R} f_{n} \rightarrow \mathbf{R} g_{1} \circ \cdots \circ \mathbf{R} g_{m} \tag{2.3}
\end{equation*}
$$

is said to be compatible with a natural transformation of compositions of the underlying abelian category functors

$$
\begin{equation*}
f_{1} \circ \cdots \circ f_{n} \rightarrow g_{1} \circ \cdots \circ g_{m} \tag{2.4}
\end{equation*}
$$

[^2]if the following diagram commutes

where $Q$ denotes localization functor from each chain homotopy category to the corresponding derived category and the vertical arrows are composed from the natural transformations $Q \circ f_{i} \rightarrow$ $\mathbf{R} f_{i} \circ Q$ and $Q \circ g_{i} \rightarrow \mathbf{R} g_{i} \circ Q$ that $\mathbf{R} f_{i}$ and $\mathbf{R} g_{i}$ come equipped with by the definition of a right derived functor. Compositions of left-derived functors are treated analogously.
(1) Commutativity and associativity of tensor product. Let $X$ be a ringed space. Then for any $A, B, C \in D\left(\mathcal{O}_{X}\right.$-Mod) there exist unique natural isomorphisms
\[

$$
\begin{equation*}
A \otimes B \xrightarrow{\sim} B \otimes A \tag{2.6}
\end{equation*}
$$

\]

and

$$
\begin{equation*}
\rho:(A \otimes B) \otimes C \xrightarrow{\sim} A \otimes B \otimes C \xrightarrow{\sim} A \otimes(B \otimes C) \tag{2.7}
\end{equation*}
$$

which are functorial in $A, B$ and $C$ and which are compatible with the corresponding natural isomorphisms for sheaves [13, Section 2.5.7 and Section 2.5.9].
(2) Sheafified $(A \otimes(-), \mathbf{R} \mathcal{H}$ om $(A,-))$ adjunction. Let $X$ be a ringed space. Then for any $A, B, C \in D\left(\mathcal{O}_{X}\right.$-Mod) there exist unique natural isomorphism

$$
\begin{equation*}
v_{A}: \mathbf{R} \mathcal{H o m}_{X}(A \otimes B, C) \xrightarrow{\sim} \mathbf{R} \mathcal{H o m}_{X}\left(B, \mathbf{R} \mathcal{H o m}_{X}(A, C)\right) \tag{2.8}
\end{equation*}
$$

compatible with the corresponding natural isomorphism for sheaves [13, Prop. 2.6.1].
Applying the derived global sections functor to (2.8) produces the adjunction isomorphism for the pair $\left(A \otimes-, \mathbf{R} \mathcal{H o m}_{X}(A,-)\right)$. We call its counit the evaluation map of $A$ and denote it by

$$
\begin{equation*}
\mathrm{ev}_{A}: A \otimes \mathbf{R} \mathcal{H o m}_{X}(A,-) \rightarrow \mathrm{Id} \tag{2.9}
\end{equation*}
$$

An important instance is the morphism $A \otimes A^{\vee} \xrightarrow{\mathrm{ev}_{A}} \mathcal{O}_{X}$ obtained by applying ev ${ }_{A}$ to $\mathcal{O}_{X}$.
(3) Perfect objects and $\mathbf{R}$ Hom. Let $X$ be a ringed space. For any $A, B, C \in D\left(\mathcal{O}_{X}\right.$-Mod) define

$$
\begin{equation*}
\xi: \mathbf{R} \mathcal{H o m}_{X}(A, B) \otimes C \longrightarrow \mathbf{R} \mathcal{H o m}_{X}(A, B \otimes C) \tag{2.10}
\end{equation*}
$$

to be the right adjoint with respect to $A \otimes(-)$ of the composition

$$
\begin{equation*}
A \otimes\left(\mathbf{R} \mathcal{H o m}_{X}(A, B) \otimes C\right) \xrightarrow{\rho^{-1}}\left(A \otimes \mathbf{R} \mathcal{H o m}_{X}(A, B)\right) \otimes C \xrightarrow{\mathrm{ev}_{A}} B \otimes C . \tag{2.11}
\end{equation*}
$$

If either of $C$ or $A$ belong to $D_{\text {perf }}(X)$, then $\xi$ is an isomorphism [3, Lemma 1.4.6]. In particular, for any $E \in D_{\text {perf }}(X)$ we have an isomorphism

$$
\begin{equation*}
\xi_{E}: E^{\vee} \otimes(-) \xrightarrow{\sim} \mathbf{R} \mathcal{H o m}_{X}(E,-) \tag{2.12}
\end{equation*}
$$

of functors $D\left(\mathcal{O}_{X}\right.$-Mod $) \rightarrow D\left(\mathcal{O}_{X}\right.$-Mod $)$.
The adjunction $\left(E \otimes-, \mathbf{R} \mathcal{H o m}_{X}(E,-)\right)$ induces via $\xi_{E}$ an adjunction $\left(E \otimes-, E^{\vee} \otimes-\right)$ whose adjunction co-unit we also denote by $\mathrm{ev}_{E}$ :

$$
\begin{equation*}
E \otimes\left(E^{\vee} \otimes-\right) \xrightarrow{\xi_{E}} E \otimes \mathbf{R} \mathcal{H o m}_{X}(E,-) \xrightarrow{\mathrm{ev}_{E}} \mathrm{Id} . \tag{2.13}
\end{equation*}
$$

(4) $\mathcal{O}_{X}$-reflexivity for perfect objects. Let $X$ be a ringed space. For any $A, B \in D\left(\mathcal{O}_{X}\right.$ - Mod $)$ define

$$
\begin{equation*}
\theta_{A, B}: A \longrightarrow \mathbf{R} \mathcal{H o m}_{X}\left(\mathbf{R} \mathcal{H o m}_{X}(A, B), B\right) \tag{2.14}
\end{equation*}
$$

to be the right adjoint with respect to $\mathbf{R} \mathcal{H o m}_{X}(A, B) \otimes(-)$ of

$$
A \otimes \mathbf{R} \mathcal{H o m}_{X}(A, B) \xrightarrow{\mathrm{ev}_{A}} B .
$$

If $B=\mathcal{O}_{X}$ the resulting morphism

$$
\begin{equation*}
\theta_{A}: A \rightarrow A^{\vee \vee} \tag{2.15}
\end{equation*}
$$

an isomorphism for all $A \in D_{\text {perf }}(X)$ [3, Prop 1.4.4].
Let $E \in D_{\text {perf. The adjunction }}\left(E^{\vee} \otimes-, E^{\vee \vee} \otimes-\right)$ induces via the isomorphism $E \xrightarrow{\theta_{E}} E^{\vee \vee}$ an adjunction ( $E^{\vee} \otimes-, E \otimes-$ ) whose adjunction co-unit we denote by ev $E^{\vee}$ :

$$
\begin{equation*}
E^{\vee} \otimes(E \otimes-) \xrightarrow{\theta_{E}} E^{\vee} \otimes\left(E^{\vee \vee} \otimes-\right) \xrightarrow{\mathrm{ev}_{E^{\vee}}} \mathrm{Id} \tag{2.16}
\end{equation*}
$$

(5) Pseudofunctoriality of direct and inverse image. Let $X, Y, Z$ be ringed spaces and $X \xrightarrow{f}$ $Y \xrightarrow{g} Z$ be maps of ringed spaces. There exist unique isomorphisms

$$
\begin{equation*}
\eta_{g, f}:(g \circ f)_{*} \xrightarrow{\sim} g_{*} f_{*} \quad \text { of functors } D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{Z}-\text { Mod }\right) \tag{2.17}
\end{equation*}
$$

and

$$
\begin{equation*}
\zeta_{g, f}: f^{*} g^{*} \xrightarrow{\sim}(g \circ f)^{*} \quad \text { of functors } D\left(\mathcal{O}_{Z}-\mathbf{M o d}\right) \rightarrow D\left(\mathcal{O}_{X}-\mathbf{M o d}\right) \tag{2.18}
\end{equation*}
$$

which are compatible with the corresponding natural isomorphisms for sheaves. These isomorphisms give $(-)_{*}$ and $(-)^{*}$ the structures of a covariant and a contravariant pseudofunctor over the category of ringed spaces [13, Section 3.6]. Specifically, for any map $X \xrightarrow{f} Y$ of ringed spaces we have

$$
\begin{equation*}
\eta_{\mathrm{Id}, f}=\eta_{f, \mathrm{Id}}=\mathrm{Id} \quad \text { and } \quad \zeta_{\mathrm{Id}, f}=\zeta_{f, \mathrm{Id}}=\mathrm{Id} \tag{2.19}
\end{equation*}
$$

and for any maps $X \xrightarrow{f} Y \xrightarrow{g} Z \xrightarrow{h} W$ of ringed spaces the following diagrams commute

We write $\eta_{h, g, f}$ for the corresponding isomorphism $(h \circ g \circ f)_{*}^{\sim} \xrightarrow{\sim} h_{*} g_{*} f_{*}$ and $\zeta_{h, g, f}$ for the corresponding isomorphism $f^{*} g^{*} h^{*} \xrightarrow{\sim}(h \circ g \circ f)^{*}$.
(6) Sheafified $\left(f^{*}, f_{*}\right)$ adjunction. Let $X, Y$ be ringed spaces and let $X \xrightarrow{f} Y$ be a map of ringed spaces. For any $A \in D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right)$ and $B \in D\left(\mathcal{O}_{X}-\mathbf{M o d}\right)$ there exists a unique bifunctorial isomorphism

$$
\begin{equation*}
\tau_{f}: f_{*} \mathbf{R} \mathcal{H o m}_{X}\left(f^{*} A, B\right) \xrightarrow{\sim} \mathbf{R} \mathcal{H o m}_{Y}\left(A, f_{*} B\right) \tag{2.21}
\end{equation*}
$$

compatible with the corresponding natural isomorphism for sheaves [13, Prop. 3.2.3].

Applying the derived global sections functor to (2.21) produces an adjunction isomorphism for the pair $\left(f^{*}, f_{*}\right)$. We denote its unit and counit by

$$
\begin{equation*}
\beta_{f}: \operatorname{Id} \rightarrow f_{*} f^{*} \quad \text { and } \quad \gamma_{f}: f^{*} f_{*} \rightarrow \operatorname{Id} \tag{2.22}
\end{equation*}
$$

The adjunction $\left(f^{*}, f_{*}\right)$ is compatible with pseudofunctoriality in the following sense. Let $X \xrightarrow{f} Y$ and $Y \xrightarrow{g} Z$ be maps of ringed spaces, then the following diagrams commute:

see [13, Section 3.6] for more details.
(7) Monoidal functor structure for inverse image. Let $X, Y$ be ringed spaces and let $X \xrightarrow{f} Y$ be a map of ringed spaces. For any $A, B \in D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right)$ there exists a unique isomorphism

$$
\begin{equation*}
v_{f}: f^{*}(A \otimes B) \xrightarrow{\sim} f^{*}(A) \otimes f^{*} B \tag{2.24}
\end{equation*}
$$

functorial in $A$ and $B$ which is compatible with the corresponding natural isomorphism for sheaves [13, Prop. 3.2.4(i)]. It is worth noting that as a natural transformation of functors in $B$ isomorphism $\nu_{f}$ is conjugate to $\tau_{f}$ in sense of [14, Section IV.7].

Map $v_{f}$ is compatible with the associativity of the tensor product in the following sense. Let $X \xrightarrow{f} Y$ be a map of ringed spaces. Then the following diagram

$$
\begin{gather*}
f^{*}((A \otimes B) \otimes C) \xrightarrow{v_{f}} f^{*}(A \otimes B) \otimes f^{*} C \xrightarrow{\nu_{f} \otimes \mathrm{Id}}\left(f^{*} A \otimes f^{*} B\right) \otimes f^{*} C  \tag{2.25}\\
\quad f^{*} \rho \downarrow \downarrow \\
f^{*}(A \otimes(B \otimes C)) \xrightarrow[v_{f}]{ } f^{*} A \otimes f^{*}(B \otimes C) \xrightarrow{\mathrm{Id} \otimes v_{f}} f^{*} A \otimes\left(f^{*} B \otimes f^{*} C\right)
\end{gather*}
$$

commutes for any $A, B, C \in D\left(\mathcal{O}_{Y}\right.$-Mod) [13, Section 3.4].
Map $v_{f}$ is compatible with pseudofunctoriality in the following sense. Let $X \xrightarrow{f} Y$ and $Y \xrightarrow{g} Z$ be maps of ringed spaces. Then the following diagram commutes

for all $A, B \in D\left(\mathcal{O}_{Z}\right.$-Mod $)$ [13, Section 3.6].
(8) Monoidal functor structure for direct image. Let $X, Y$ be ringed spaces and let $X \xrightarrow{f} Y$ be a map of ringed spaces. For any $A, B \in D\left(\mathcal{O}_{X}\right.$-Mod) define morphism

$$
\begin{equation*}
\kappa_{f}: f_{*} A \otimes f_{*} B \rightarrow f_{*}(A \otimes B) \tag{2.27}
\end{equation*}
$$

functorial in $A$ and $B$, to be the right adjoint with respect to $f^{*}$ of the composition

$$
f^{*}\left(f_{*} A \otimes f_{*} B\right) \xrightarrow{\nu_{f}} f^{*} f_{*} A \otimes f^{*} f_{*} B \xrightarrow{\gamma_{f} \otimes \gamma_{f}} A \otimes B
$$

Map $\kappa_{f}$ is compatible with the associativity of the tensor product and with pseudofunctoriality in a way analogous to map $v_{f}$ [13, Section 3.4 and Section 3.6].
(9) Projection formula. Let $X, Y$ be ringed spaces and let $X \xrightarrow{f} Y$ be a map of ringed spaces. For any $A \in D\left(\mathcal{O}_{X}\right.$-Mod) and $B \in D\left(\mathcal{O}_{Y}\right.$-Mod) define the projection formula morphism

$$
\begin{equation*}
\alpha_{f}: f_{*} A \otimes B \rightarrow f_{*}\left(A \otimes f^{*} B\right) \tag{2.28}
\end{equation*}
$$

to be the right adjoint with respect to $f^{*}$ of the composition

$$
f^{*}\left(f_{*} A \otimes B\right) \xrightarrow{\nu_{f}} f^{*} f_{*} A \otimes f^{*} B \xrightarrow{\gamma_{f} \otimes \mathrm{Id}} A \otimes f^{*} B .
$$

If $X$ and $Y$ are concentrated schemes, then $\alpha_{f}$ is an isomorphism for all $A \in D_{q c}(X)$ and $B \in D_{q c}(Y)$ [13, Prop. 3.9.4].

The projection formula is compatible with pseudofunctoriality in the following sense. Let $X \xrightarrow{f} Y$ and $Y \xrightarrow{g} Z$ be maps of ringed spaces. Then the following diagram

$$
\begin{aligned}
& A \otimes(g \circ f)_{*} B \underset{\alpha_{g \circ f}}{ }(g \circ f)_{*}\left((g \circ f)^{*} A \otimes B\right) \xrightarrow[\eta_{g \circ f}]{\simeq} g_{*} f_{*}\left((g \circ f)^{*} A \otimes B\right)
\end{aligned}
$$

commutes for any $A \in D\left(\mathcal{O}_{Z}-\mathbf{M o d}\right)$ and $B \in D\left(\mathcal{O}_{X}\right.$-Mod) [13, Prop. 3.7.1].
(10) The sheafified Grothendieck duality morphism. Let $X$ and $Y$ be concentrated schemes and let $X \xrightarrow{f} Y$ be a map of schemes. Denote the unit and counit of the $\left(f_{*}, f^{\times}\right)$adjunction by

$$
\begin{equation*}
\lambda_{f}: \operatorname{Id} \rightarrow f^{\times} f_{*} \quad \text { and } \quad \epsilon_{f}: f_{*} f^{\times} \rightarrow \mathrm{Id} \tag{2.30}
\end{equation*}
$$

The $\left(f_{*}, f^{\times}\right)$adjunction is compatible with pseudofunctoriality, in the sense that the analogues of diagrams (2.23) for $\delta_{f}$ and $\lambda_{f}$ also commute, see [13, Cor. 4.1.2] for more details.

Define for any $A \in D_{q c}(X)$ and $B \in D_{q c}(Y)$ the sheafified Grothendieck duality morphism

$$
\begin{equation*}
\delta_{f}: f_{*} \mathbf{R} \mathcal{H o m}_{X}\left(A, f^{\times} B\right) \rightarrow \mathbf{R} \mathcal{H o m}_{Y}\left(f_{*} A, B\right) \tag{2.31}
\end{equation*}
$$

to be the composition

$$
\begin{aligned}
f_{*} \mathbf{R} \mathcal{H o m}_{X}\left(A, f^{\times} B\right) & \xrightarrow{\gamma_{f}} f_{*} \mathbf{R} \mathcal{H o m}_{X}\left(f^{*} f_{*} A, f^{\times} B\right) \\
& \xrightarrow{\tau_{f}} \mathbf{R} \mathcal{H o m}\left(f_{*} A, f_{*} f^{\times} B\right) \xrightarrow{\epsilon_{f}} \mathbf{R} \mathcal{H o m}\left(f_{*} A, B\right) .
\end{aligned}
$$

When $X$ and $Y$ are noetherian and $f$ is proper $\delta_{f}$ is an isomorphism for all $A \in D_{\mathrm{qc}}(X)$ and $B \in D_{\mathrm{qc}}^{+}(Y)$ [13, Theorem. 4.4.1]. If, in addition to the above, $f$ is perfect, $\delta_{f}$ is an isomorphism for all $A \in D_{\mathrm{qc}}(X)$ and $B \in D_{\mathrm{qc}}(X)$ [13, Theorem 4.7.4].
(11) Let $X, Y$ be concentrated schemes and let $X \xrightarrow{f} Y$ be a map of schemes. For any $A \in D_{q c}(X)$ and $B \in D_{q c}(Y)$ define morphism

$$
\begin{equation*}
\chi_{f}: f^{\times} A \otimes f^{*} B \rightarrow f^{\times}(A \otimes B) \tag{2.32}
\end{equation*}
$$

functorial in $A$ and $B$ to be the right adjoint with respect to $f_{*}$ of the composition

$$
f_{*}\left(f^{\times} A \otimes f^{*} B\right) \xrightarrow{\alpha_{f}^{-1}} f_{*} f^{\times} A \otimes B \xrightarrow{\epsilon_{f} \otimes \mathrm{Id}} A \otimes B
$$

where $\alpha_{f}^{-1}$ is the inverse of the projection formula isomorphism. When $f$ is proper and perfect $\chi_{f}$ is an isomorphism [13, Exercise 4.7.3.4(a)].
(12) Base change. Let $\sigma$ be a commutative square

of ringed spaces. We define the base change morphism

$$
\begin{equation*}
\mu_{\sigma}: g^{*} f_{*} \rightarrow f_{*}^{\prime} g^{*} \tag{2.34}
\end{equation*}
$$

to be the right adjoint with respect to $f^{* *}$ of the composition

$$
f^{\prime *} g^{*} f_{*} \xrightarrow{\zeta_{g, f^{\prime}}}\left(g \circ f^{\prime}\right)^{*} f_{*}=\left(f \circ g^{\prime}\right)^{*} f_{*} \xrightarrow{\zeta_{f, g^{\prime}}^{-1}} g^{*} f^{*} f_{*} \xrightarrow{\gamma_{f}} g^{*}
$$

or, equivalently [13, Prop. 3.7.2], the left adjoint with respect to $g_{*}$ of the composition

$$
f_{*} \xrightarrow{\beta_{g^{\prime}}} f_{*} g_{*}^{\prime} g^{\prime *} \xrightarrow{\eta_{f, g^{\prime}}^{-1}}\left(f \circ g^{\prime}\right)_{*} g^{\prime *}=\left(g \circ f^{\prime}\right)_{*} g^{*} \xrightarrow{\eta_{g, f^{\prime}}} g_{*} f_{*}^{\prime} g^{\prime *} .
$$

This defines $\mu_{\sigma}$ as a morphism of functors $D\left(\mathcal{O}_{X}\right.$-Mod $) \rightarrow D\left(\mathcal{O}_{Y}^{\prime}-\right.$ Mod $)$. When $\sigma$ is a square of concentrated schemes the base change map restricts to a morphism of functors $D_{q c}(X) \rightarrow D_{q c}\left(Y^{\prime}\right)$.

We use $\sigma^{T}$ to denote the transposed square

In particular, we denote by $\mu_{\sigma^{T}}$ the base change map $f^{*} g_{*} \rightarrow f^{*} g_{*}^{\prime}$ for $\sigma^{T}$.
If the restriction of $\mu_{\sigma}$ to complexes with quasi-coherent cohomology is an isomorphism, then $\sigma$ is said to be independent. A fiber-square of concentrated schemes is independent if and only if it is Tor-independent, i.e. for any $x \in X$ and $y^{\prime} \in Y^{\prime}$ such that $f(x)=g\left(y^{\prime}\right)=$ $y \in Y$ we have

$$
\begin{equation*}
\operatorname{Tor}_{\mathcal{O}_{Y, y}}^{i}\left(\mathcal{O}_{X, x}, \mathcal{O}_{Y^{\prime}, y^{\prime}}\right)=0 \quad \text { for all } i>0 \tag{2.36}
\end{equation*}
$$

cf. [13, Theorem 3.10.3]. In particular, a fiber-square of concentrated schemes is independent if $f$ or $g$ are flat. Another good reference for the above material is [12, Section 2.4], where the proofs are carried out via computations with the underlying Fourier-Mukai kernels.

### 2.4. Further relations

To prove our main results in Section 3 we need three technical results which we could not find in the literature. The first two state that the projection formula commutes with certain adjunction units and counits of the direct image functor.

Lemma 2.1. Let $X \xrightarrow{g} Y \xrightarrow{f} Z$ be maps of ringed spaces. Let $A \in D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right)$ and $B \in D\left(\mathcal{O}_{Z}-\mathrm{Mod}\right)$. Then the following diagram commutes:

Proof. By functoriality of $\alpha_{f}$ it suffices to show that the square

commutes. This square is the image under $f_{*}$ of the square

To show that (2.38) commutes we show that its left adjoint with respect to $g_{*}$ commutes. By definition of $\alpha_{g}$ its left adjoint with respect to $g_{*}$ is $\left(\gamma_{g} \otimes \mathrm{Id}\right) \circ v_{g}$. So the left adjoint with respect to $g_{*}$ of (2.38) is
and by functoriality of $\nu_{g}$ it suffices to show that the following composition is the identity morphism:

$$
g^{*} A \otimes g^{*} f^{*} B \xrightarrow{g^{*} \beta_{g} \otimes \mathrm{Id}} g^{*} g_{*} g^{*} A \otimes g^{*} f^{*} B \xrightarrow{\gamma_{g} \otimes \mathrm{Id}} g^{*} A \otimes g^{*} f^{*} B .
$$

Rewrite it as $\left(g^{*} \beta_{g} \circ \gamma_{g}\right) \otimes$ Id. Since $\beta_{g}$ and $\gamma_{g}$ are the unit and the counit of the adjunction $\left(g^{*}, g_{*}\right)$, the morphism $g^{*} A \xrightarrow{g^{*} \beta_{g} \circ \gamma_{g}} g^{*} A$ is the identity morphism. The result follows.

Lemma 2.2. Let $X, Y, Z$ be concentrated schemes and $X \xrightarrow{g} Y \xrightarrow{f} Z$ be scheme maps. Let $A \in D_{q c}(Y)$ and $B \in D_{q c}(Z)$. Then the following diagram commutes:

$$
\begin{gather*}
f_{*} g_{*} g^{\times} A \otimes B \xrightarrow[f_{*}]{f_{*} \epsilon_{g} \otimes \mathrm{Id}} \quad f_{*} A \otimes B \\
f_{*} \alpha_{g} \circ \alpha_{f} \downarrow \downarrow  \tag{2.39}\\
f_{*} g_{*}\left(g^{\times} A \otimes g^{*} f^{*} B\right) \underset{f_{*} g_{*} \chi_{g}}{\longrightarrow} f_{*} g_{*} g^{\times}\left(A \otimes f^{*} B\right) \underset{f_{*} \epsilon_{g}}{\longrightarrow} f_{*}\left(A \otimes f^{*} B\right) .
\end{gather*}
$$

Proof. The proof is analogous to that of Lemma 2.1. By functoriality of $\alpha_{f}$ it suffices to show that the image under $f_{*}$ of

$$
\begin{aligned}
& g_{*} g^{\times} A \otimes f^{*} B \epsilon_{g} \\
& \downarrow \\
& g_{*}\left(g^{\times} A \otimes g^{*} f^{*} B\right) \underset{g_{*} \chi_{g}}{\longrightarrow} g_{*} g^{\times}\left(A \otimes f^{*} B\right) \underset{\epsilon_{g}}{\longrightarrow} \epsilon_{\mathrm{I}} \\
& \longrightarrow
\end{aligned} \otimes f^{*} B
$$

commutes. Since $\alpha_{g}$ is an isomorphism, this is equivalent to the diagram

$$
\begin{gathered}
g_{*} g^{\times} A \otimes f^{*} B \\
g_{*}^{\alpha_{g}^{-1}} \uparrow \\
g_{*}\left(g^{\times} A \otimes g^{*} f^{*} B\right) \underset{g_{*} \chi_{g}}{\longrightarrow} g_{*} g^{\times}\left(A \otimes f^{*} B\right) \underset{\epsilon_{g}}{\longrightarrow} A \otimes f^{*} B
\end{gathered}
$$

commuting. But as $\epsilon_{g}$ is the adjunction counit, the composition $\epsilon_{g} \circ g_{*} \chi_{g}$ is the left adjoint of $\chi_{g}$ with respect to $g^{\times}$. By the definition of $\chi_{g}$ this left adjoint is precisely $\left(\epsilon_{g} \otimes \mathrm{Id}\right) \circ \alpha_{g}^{-1}$. The result follows.

The third result shows that for a perfect object $E$ the adjunction co-units for $E \otimes(-)$ commute with the associativity of the tensor product:

Lemma 2.3. Let $X$ be a ringed space. Then for any $A \in D\left(\mathcal{O}_{X}-\operatorname{Mod}\right)$ and $E \in D_{p e r f}(X)$ the following diagrams commute

Proof. The adjunction counit $E \otimes\left(E^{\vee} \otimes A\right) \xrightarrow{\text { ev }} A$ was defined as the composition

$$
E \otimes\left(E^{\vee} \otimes A\right) \xrightarrow[\sim]{\mathrm{Id} \otimes \xi_{E}} \underset{\sim}{\sim} \otimes \mathbf{R} \mathcal{H} \mathrm{om}(E, A) \xrightarrow{\mathrm{ev}_{E}} A
$$

Therefore its right adjoint with respect to $E \otimes(-)$ is isomorphism $\xi_{E}$. But isomorphism $\xi_{E}$ was defined to be the right adjoint with respect to $E \otimes(-)$ of the composition

$$
E \otimes\left(E^{\vee} \otimes A\right) \xrightarrow{\rho^{-1}}\left(E \otimes E^{\vee}\right) \otimes A \xrightarrow{\operatorname{ev}_{E}\left(\mathcal{O}_{X}\right) \otimes \mathrm{Id}} A
$$

Therefore the left diagram commutes.
For the right diagram, recall that by its definition the adjunction co-unit $E^{\vee} \otimes(E \otimes A) \xrightarrow{\mathrm{ev}_{E^{\vee}}} \mathrm{Id}$ is

$$
E^{\vee} \otimes(E \otimes A) \xrightarrow[\sim]{\left(\mathrm{Id} \otimes \theta_{E}\right) \otimes \mathrm{Id}} E^{\vee} \otimes\left(E^{\vee \vee} \otimes A\right) \xrightarrow{\mathrm{ev}_{E^{\vee}}} A
$$

Since the left diagram commutes and $\rho$ is functorial, we can rewrite the composition above as

$$
E^{\vee} \otimes(E \otimes A) \xrightarrow{\rho^{-1}}\left(E^{\vee} \otimes E\right) \otimes A \xrightarrow[\sim]{\sim}\left(E^{\vee} \otimes E^{\vee \vee}\right) \otimes A \xrightarrow{\operatorname{ev}_{E^{\vee}}\left(\mathcal{O}_{X}\right)} A
$$

To show that the right diagram commutes it now remains only to show that

$$
E^{\vee} \otimes E \xrightarrow[\sim]{\mathrm{Id} \otimes \theta_{E}} E^{\vee} \otimes E^{\vee \vee} \xrightarrow{\mathrm{ev}_{E^{\vee}}\left(\mathcal{O}_{X}\right)} \mathcal{O}_{X}
$$

is the map $E^{\vee} \otimes E \xrightarrow{\operatorname{ev}_{E}\left(\mathcal{O}_{X}\right)} \mathcal{O}_{X}$. The right adjoint of the composition above with respect to $E^{\vee} \otimes(-)$ is just the map $E \xrightarrow{\theta_{E}} E^{\vee \vee}$. But $\theta_{E}$ was defined as the right adjoint with respect to $E^{\vee} \otimes(-)$ of $E^{\vee} \otimes E \xrightarrow{\operatorname{ev}_{E}\left(\mathcal{O}_{X}\right)} \mathcal{O}_{X}$. The claim follows.

Define a morphism

$$
\begin{equation*}
\mathrm{ev}_{E}: E^{\vee} \otimes E \otimes(-) \longrightarrow \mathrm{Id} \tag{2.41}
\end{equation*}
$$

to be the composition

$$
E^{\vee} \otimes E \otimes(-) \xrightarrow[\sim]{\rho}\left(E^{\vee} \otimes E\right) \otimes(-) \xrightarrow{\mathrm{ev}_{E}\left(\mathcal{O}_{X}\right) \otimes \mathrm{Id}} \mathrm{Id}
$$

By Lemma 2.3 the canonical isomorphisms identifying $E^{\vee} \otimes E \otimes-$ with $E^{\vee} \otimes(E \otimes-)$ and $E \otimes\left(E^{\vee} \otimes-\right)$ identify (2.41) with the adjunction counits for the adjunctions ( $E^{\vee} \otimes-, E \otimes-$ ) and ( $E \otimes-, E^{\vee} \otimes-$ ), respectively. We thus abuse notation by speaking of (2.41) as "the adjunction counit" for these two adjunctions.

## 3. Adjunction morphisms for Fourier-Mukai transforms

### 3.1. Compact case

Let $X_{1}$ and $X_{2}$ be a pair of separable schemes of finite type over an algebraically closed field $k$ of characteristic 0 with $X_{2}$ proper. We have the following commutative diagram

All the morphisms in it are separated and of finite-type. They are also flat, and therefore perfect. Moreover, morphisms $\pi_{1}$ and $\pi_{13}$ are proper.

Definition 3.1. Let $E$ be a perfect object of $D\left(X_{1} \times X_{2}\right)$. The Fourier-Mukai transform $\Phi_{E}$ from $X_{1}$ to $X_{2}$ with kernel $E$ is the functor $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{2}\right)$ given by

$$
\Phi_{E}(-)=\pi_{2 *}\left(E \otimes \pi_{1}^{*}(-)\right) .
$$

By the adjunctions described in Section 2.2 functor $\Phi_{E}$ has both left and right adjoints. The left adjoint $\Phi_{E}^{\text {ladj }}$ is isomorphic to the Fourier-Mukai transform from $X_{2}$ to $X_{1}$ with kernel $E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)$. The composition $\Phi_{E}^{\text {ladj }} \Phi_{E}$ is then isomorphic [15, Prop 1.3] to the Fourier-Mukai transform from $X_{1}$ to $X_{1}$ with kernel

$$
Q=\pi_{13 *}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) .
$$

Let now $\Delta$ denote the diagonal inclusion $X_{1} \hookrightarrow X_{1} \times X_{1}$ and, by abuse of notation, let it also denote the induced inclusion $X_{1} \times X_{2} \hookrightarrow X_{1} \times X_{2} \times X_{1}$, so that there is the following fiber square:

The identity functor Id is isomorphic to the Fourier-Mukai transform from $X_{1}$ to $X_{1}$ with kernel $\Delta_{*} \mathcal{O}_{X_{1}}$. We now state the main result of this section:

Theorem 3.1. Let $X_{1}$ and $X_{2}$ be two separable schemes of finite type over $k$ with $X_{2}$ proper. Let $E$ be a perfect object of $D\left(X_{1} \times X_{2}\right)$ and $\Phi_{E}$ be a Fourier-Mukai transform from $D_{q c}\left(X_{1}\right)$ to $D_{q c}\left(X_{2}\right)$ defined by $E$.

The adjunction counit $\gamma_{E}: \Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id is isomorphic to the morphism of Fourier-Mukai transforms $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{1}\right)$ induced by the following morphism of their kernels:

$$
\begin{align*}
& Q=\pi_{13 *}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \\
& \xrightarrow{\pi_{13 *} \beta \Delta} \pi_{13 *} \Delta_{*} \Delta^{*}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{3.3}\\
& \pi_{13 *} \Delta_{*} \Delta^{*}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \simeq \Delta_{*} \pi_{1 *}\left(E \otimes E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{3.4}\\
& \Delta_{*} \pi_{1 *}\left(E \otimes E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \xrightarrow{\Delta_{*} \pi_{1 *}{ }^{\mathrm{ev}}{ }_{E}} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{3.5}\\
& \Delta_{*} \pi_{1 *} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right) \xrightarrow{\Delta_{*} \epsilon_{\pi_{1}}} \Delta_{*} \mathcal{O}_{X_{1}} \tag{3.6}
\end{align*}
$$

where (3.4) is composed of isomorphism $\nu_{\Delta}: \Delta^{*}(-\otimes-) \xrightarrow{\sim} \Delta^{*}(-) \otimes \Delta^{*}(-)$ and of pseudofunctoriality isomorphisms corresponding to the identities $\pi_{13} \circ \Delta=\Delta \circ \pi_{1}$ and $\pi_{12} \circ \Delta=\pi_{23} \circ \Delta=\mathrm{Id}$.

We first need the following crucial lemma:

Lemma 3.2. Let $\sigma$ be the fiber square

Then the following diagram of functors commutes:

$$
\begin{align*}
& \pi_{2}^{*} \pi_{2 *} \xrightarrow{\gamma_{\pi_{2}}} \text { Id }  \tag{3.8}\\
& \mu_{\sigma} \mid \simeq \\
& \downarrow \simeq \eta_{\pi_{23}, \Delta \circ \zeta_{\pi_{12}, \Delta}^{-1}} \\
& \pi_{23 *} \pi_{12}^{*} \underset{\pi_{23 *} \beta_{\Delta}}{\longrightarrow} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*} .
\end{align*}
$$

Proof. It suffices to show that the right adjoints with respect to $\pi_{2}^{*}$ of the composition

$$
\begin{equation*}
\pi_{2}^{*} \pi_{2 *} \xrightarrow{\mu} \pi_{23 *} \pi_{12}^{*} \xrightarrow{\pi_{23 *} \beta_{\Delta}} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*} \tag{3.9}
\end{equation*}
$$

and of the composition

$$
\begin{equation*}
\pi_{2}^{*} \pi_{2 *} \xrightarrow{\gamma_{\pi_{2}}} \mathrm{Id} \xrightarrow{\eta_{\pi_{23}, \Delta \circ} \circ \zeta_{\pi_{12}, \Delta}^{-1}} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*} \tag{3.10}
\end{equation*}
$$

coincide. By the definition of morphism $\mu_{\sigma}$ the right adjoint with respect to $\pi_{2}^{*}$ of (3.9) is

$$
\pi_{2 *} \xrightarrow{\pi_{2 *} \beta_{\pi_{12}}} \pi_{2 *} \pi_{12 *} \pi_{12}^{*} \xrightarrow{\eta_{\pi_{2}, \pi_{23}} \circ \eta_{\pi_{2}, \pi_{12}}^{1}} \pi_{2 *} \pi_{23 *} \pi_{12}^{*} \xrightarrow{\pi_{2 *} \pi_{23 *} \beta_{\Delta}} \pi_{2 *} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*}
$$

which by functoriality of $\eta_{\pi_{2}, \pi_{23}} \circ \eta_{\pi_{2}, \pi_{12}}^{-1}$ is the same as

$$
\begin{align*}
\pi_{2 *} & \xrightarrow{\pi_{2 *} \beta_{\pi_{12}}} \pi_{2 *} \pi_{12 *} \pi_{12}^{*} \\
& \xrightarrow{\pi_{2 *} \pi_{12 *} \beta_{\Delta}} \pi_{2 *} \pi_{12 *} \Delta_{*} \Delta^{*} \pi_{12}^{*} \xrightarrow{\eta_{\pi_{2}, \pi_{23} \circ \eta_{\pi_{2}, \pi_{12}}^{-1}}^{\longrightarrow} \pi_{2 *} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*} .} \tag{3.11}
\end{align*}
$$

By pseudofunctoriality of the direct image, cf. (2.20), the morphism of functors

$$
\pi_{2 *} \pi_{12 *} \Delta_{*} \xrightarrow{\eta_{\pi_{2}, \pi_{23}} \circ \eta_{\pi_{2}, \pi_{12}}^{-1}} \pi_{2 *} \pi_{23 *} \Delta_{*}
$$

is the same as the morphism of functors

$$
\pi_{2 *} \pi_{12 *} \Delta_{*} \xrightarrow{\pi_{2 *}\left(\eta_{\pi_{23}, \Delta} \circ \eta_{\pi_{12}, \Delta}^{-1}\right)} \pi_{2 *} \pi_{23 *} \Delta_{*}
$$

and we can therefore rewrite (3.11) as

$$
\begin{equation*}
\pi_{2 *}\left(\operatorname{Id} \xrightarrow{\beta_{\pi_{12}}} \pi_{12 *} \pi_{12}^{*} \xrightarrow{\pi_{12 *} \beta_{\Delta}} \pi_{12 *} \Delta_{*} \Delta^{*} \pi_{12}^{*} \xrightarrow{\eta_{\pi_{23},}, \Delta^{\circ} \eta_{12}^{-1} \pi_{\Delta}} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*}\right) . \tag{3.12}
\end{equation*}
$$

By the compatibility of $\beta$ with pseudofunctoriality as per diagram (2.23) we can rewrite (3.12) as

$$
\begin{aligned}
& \pi_{2 *}\left(\operatorname{Id} \xrightarrow{\beta_{\pi_{12} \circ}}\left(\pi_{12} \circ \Delta\right)_{*}\left(\pi_{12} \circ \Delta\right)^{*} \xrightarrow{\eta_{\pi_{12}, \Delta \circ \zeta_{\pi_{12}, \Delta}^{-1}}^{\longrightarrow}} \pi_{12 *} \Delta_{*} \Delta^{*} \pi_{12}^{*}\right. \\
& \left.\xrightarrow{\eta_{\pi_{23}, \Delta \circ \eta_{\pi_{12}, \Delta}^{-1}}^{l}} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*}\right) .
\end{aligned}
$$

Cancelling out $\eta_{\pi_{12}, \Delta}^{-1} \circ \eta_{\pi_{12}, \Delta}$ and noting that $\beta_{\pi_{12} \circ \Delta}=\mathrm{Id}$ since $\pi_{12} \circ \Delta=$ Id yields

$$
\pi_{2 *}\left(\operatorname{Id} \xrightarrow{\eta_{\pi_{23}, \Delta \circ \zeta_{\pi_{12}, \Delta}^{-1}}} \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*}\right)
$$

which is clearly the right adjoint of (3.10) with respect to $\pi_{2}^{*}$. The result follows.
Proof of Theorem 3.1. Set

$$
Q^{\prime}=\pi_{23}^{*}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee}\right) \otimes \pi_{12}^{*} E
$$

so that $Q=\pi_{13 *} Q^{\prime}$. Since $\pi_{12} \circ \Delta=\pi_{23} \circ \Delta=\mathrm{Id}$ we have a natural isomorphism

$$
\begin{equation*}
\Delta^{*} Q^{\prime} \xrightarrow{\nu_{\Delta}} \Delta^{*} \pi_{23}^{*}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee}\right) \otimes \Delta^{*} \pi_{12}^{*} E \xrightarrow{\zeta_{\pi_{23}, \Delta \otimes \zeta_{12}, \Delta}} \pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee} \otimes E . \tag{3.13}
\end{equation*}
$$

We therefore define a morphism

$$
\begin{equation*}
\Delta^{*} Q^{\prime} \xrightarrow{(3.13)} \pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee} \otimes E \xrightarrow{\mathrm{ev}_{E}} \pi_{1}^{!} \mathcal{O}_{X_{1}} \tag{3.14}
\end{equation*}
$$

Let us write the morphism of functors induced by the morphism $Q \xrightarrow{(3.3)-(3.6)} \Delta_{*} \mathcal{O}_{X_{1}}$ of FM-kernels as:

$$
\begin{align*}
& \tilde{\pi}_{2 *}\left(\pi_{13 *} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\beta_{\Delta}} \tilde{\pi}_{2 *}\left(\pi_{13 *} \Delta_{*} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right)  \tag{3.15}\\
& \tilde{\pi}_{2 *}\left(\pi_{13 *} \Delta_{*} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\eta_{\Delta, \pi_{1}} \eta_{\pi_{13}, \Delta}^{-1}} \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right)  \tag{3.16}\\
& \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{(3.14)} \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \tilde{\pi}_{1}^{*}(-)\right)  \tag{3.17}\\
& \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\epsilon_{\pi_{1}}} \tilde{\pi}_{2 *}\left(\Delta_{*} \mathcal{O}_{X_{1}} \otimes \tilde{\pi}_{1}^{*}(-)\right) . \tag{3.18}
\end{align*}
$$

On the other hand, $\Phi_{E}$ is the composition of functors $\pi_{1}^{*}, E \otimes(-)$ and $\pi_{2 *}$. Each of these functors has a left adjoint, these adjoints are $\pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes-\right), E^{\vee} \otimes(-)$ and $\pi_{2}^{*}$, respectively. Therefore, the adjunction counit $\Phi_{E}^{l a d j} \Phi_{E} \rightarrow$ Id is the composition of the three corresponding adjunction counits:

$$
\begin{align*}
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee} \otimes \pi_{2}^{*} \pi_{2 *}\left(E \otimes \pi_{1}^{*}(-)\right)\right) \xrightarrow{\gamma_{\pi_{2}}} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee} \otimes E \otimes \pi_{1}^{*}(-)\right)  \tag{3.19}\\
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee} \otimes E \otimes \pi_{1}^{*}(-)\right) \xrightarrow{\mathrm{ev}_{E}} \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*}(-)\right)  \tag{3.20}\\
& \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*}(-)\right) \xrightarrow{\epsilon_{\pi_{1}} \circ \chi_{\pi_{1}}} \mathrm{Id} . \tag{3.21}
\end{align*}
$$

The claim of the theorem is that the composition (3.19)-(3.21) is isomorphic to the composition (3.15)-(3.18).

Let us clarify some terminology. We say that two morphisms of functors $f \rightarrow g$ and $f^{\prime} \rightarrow g^{\prime}$ are isomorphic if there exist connecting isomorphisms $f \xrightarrow{\sim} f^{\prime}$ and $g \xrightarrow{\sim} g^{\prime}$ such that the diagram

commutes. Clearly it is an equivalence relation on the set of all morphisms between all functors between two given categories. In particular, it is transitive.

If we further have a morphism of functors $g \rightarrow h$ which is isomorphic to a morphism of functors $g^{\prime \prime} \rightarrow h^{\prime \prime}$ then $f \rightarrow g \rightarrow h$ is isomorphic to $f^{\prime} \rightarrow g^{\prime} \xrightarrow{\sim} g^{\prime \prime} \rightarrow h^{\prime \prime}$, where the connecting isomorphism $g^{\prime} \xrightarrow{\sim} g^{\prime \prime}$ is the composition of the inverse of the connecting isomorphism $g \xrightarrow{\sim} g^{\prime}$ with the connecting isomorphism $g \xrightarrow{\sim} g^{\prime \prime}$.

Our strategy therefore is to consecutively replace the morphisms which compose (3.19)-(3.21) by isomorphic ones until we obtain (3.15)-(3.18). However, every time we replace a composant by an isomorphic one, we introduce a new connecting isomorphism. In the end we have to compose a long chain of these isomorphisms (each composed of natural isomorphisms detailed in Section 2.3) and simplify the result. It is a mechanical exercise in pseudofunctoriality of direct and inverse image and the associativity of tensor product. To present it in full detail would be very tedious, the end result being always obvious from the start. This had long been lamented in the literature, cf. [7, Section II.6]. To keep the focus on the substance of a proof we only state the final result of each such computation of a connecting isomorphism, unless something nontrivial is involved. For our most meticulous readers (and our most inquisitive referees) we have included in the Appendix an unabbreviated proof, where all such computations are carried out in full detail.

We begin with morphism (3.19). By Lemma 3.2 it is isomorphic to

$$
\begin{align*}
& \pi_{1 *}\left(E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{23 *} \pi_{12}^{*}\left(E \otimes \pi_{1}^{*}(-)\right)\right) \\
& \stackrel{\beta_{\Delta}}{\longrightarrow} \pi_{1 *}\left(E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{23 *} \Delta_{*} \Delta^{*} \pi_{12}^{*}\left(E \otimes \pi_{1}^{*}(-)\right)\right) . \tag{3.23}
\end{align*}
$$

By Lemma 2.1 morphism (3.23) is further isomorphic to

$$
\begin{equation*}
\pi_{1 *} \pi_{23_{*}}\left(Q^{\prime} \otimes \pi_{12}^{*} \pi_{1}^{*}(-)\right) \xrightarrow{v_{\Delta} \circ \beta_{\Delta}} \pi_{1 *} \pi_{23_{*}} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) \tag{3.24}
\end{equation*}
$$

Finally, since $\pi_{1} \circ \pi_{23}=\tilde{\pi}_{2} \circ \pi_{13}$ and $\pi_{1} \circ \pi_{12}=\tilde{\pi}_{1} \circ \pi_{13}$, see diagram (3.1), the corresponding pseudofunctoriality isomorphisms imply that (3.24) is isomorphic to

$$
\begin{equation*}
\tilde{\pi}_{2 *} \pi_{13 *}\left(Q^{\prime} \otimes \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\nu_{\Delta} \circ \beta_{\Delta}} \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) . \tag{3.25}
\end{equation*}
$$

We proceed to morphism (3.20) which is induced by the adjunction counit $\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee} \otimes E \rightarrow$ $\pi_{1}^{!} \mathcal{O}_{X_{1}}$. By its definition morphism (3.14) is isomorphic to this adjunction counit, and so (3.20) is isomorphic to

$$
\begin{equation*}
\pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*}(-)\right) \xrightarrow{(3.14)} \pi_{1 *}\left(\pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right) \otimes \pi_{1}^{*}(-)\right) . \tag{3.26}
\end{equation*}
$$

As $\tilde{\pi}_{2} \circ \Delta=\tilde{\pi}_{1} \circ \Delta=$ Id by pseudofunctoriality (3.26) is isomorphic to

$$
\begin{equation*}
\tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{(3.14)} \tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) . \tag{3.27}
\end{equation*}
$$

Finally, the same pseudofunctoriality isomorphisms imply that (3.21) is isomorphic to

$$
\begin{equation*}
\tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*} \Delta_{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\epsilon_{\pi_{1}} \circ \chi_{\pi_{1}}} \tilde{\pi}_{2 *} \Delta_{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-) . \tag{3.28}
\end{equation*}
$$

We have now shown that (3.19)-(3.21) are isomorphic to (3.25), (3.27) and (3.28), respectively. Next, we compute the connecting isomorphisms. The isomorphism connecting (3.25)-(3.27) works out to be the pseudofunctoriality isomorphism

$$
\begin{align*}
& \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \\
& \stackrel{\eta_{\Delta, \pi_{1} \circ \eta_{\pi_{13}, \Delta}^{-1}}^{\longrightarrow} \tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right)}{ } \tag{3.29}
\end{align*}
$$

and the isomorphism connecting (3.27)-(3.28) works out to be the identity.
We can now conclude that the adjunction counit $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id, being the composition of (3.19)-(3.21), is isomorphic to the composition of (3.25), (3.29), (3.27) and (3.28). The claim of the theorem then follows from the fact that the following diagram commutes:

where the horizontal isomorphisms are all due to the projection formula. To see that diagram (3.30) indeed commutes, observe that its topmost square commutes by Lemma 2.1, the middle two commute by functoriality and the lowermost square commutes by Lemma 2.2.

An identical proof yields an analogous result for the right adjunction counit:
Theorem 3.2. Let $X_{1}$ and $X_{2}$ be two separable schemes of finite type over $k$ with $X_{2}$ proper. Let $E$ be a perfect object of $D\left(X_{1} \times X_{2}\right)$ and $\Psi_{E}$ be a Fourier-Mukai transform from $D_{q c}\left(X_{2}\right)$ to $D_{q c}\left(X_{1}\right)$ defined by $E$.

The adjunction counit $\gamma_{E}^{\prime}: \Psi_{E} \Psi_{E}^{\text {radj }} \rightarrow$ Id is isomorphic to the morphism of Fourier-Mukai transforms $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{1}\right)$ induced by the following morphism of objects of $D\left(X_{1} \times X_{1}\right)$ :

$$
\begin{align*}
& \tilde{Q}=\pi_{13 *}\left(\pi_{12}^{*} E^{\vee} \otimes \pi_{23}^{*} E \otimes \pi_{12}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \\
& \stackrel{\pi_{13 *} \beta \Delta}{\longrightarrow} \pi_{13 *} \Delta_{*} \Delta^{*}\left(\pi_{12}^{*} E^{\vee} \otimes \pi_{23}^{*} E \otimes \pi_{12}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{3.31}\\
& \pi_{13 *} \Delta_{*} \Delta^{*}\left(\pi_{12}^{*} E^{\vee} \otimes \pi_{23}^{*} E \otimes \pi_{12}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \simeq \Delta_{*} \pi_{1 *}\left(E \otimes E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{3.32}\\
& \Delta_{*} \pi_{1 *}\left(E \otimes E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) \xrightarrow{\Delta_{*} \pi_{1 *} \mathrm{~V}_{E}} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{3.33}\\
& \Delta_{*} \pi_{1 *} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right) \xrightarrow{\Delta_{*} \epsilon_{\pi_{1}}} \Delta_{*} \mathcal{O}_{X_{1}} \tag{3.34}
\end{align*}
$$

where (3.32) is composed of isomorphism $\nu_{\Delta}: \Delta^{*}(-\otimes-) \xrightarrow{\sim} \Delta^{*}(-) \otimes \Delta^{*}(-)$ and of pseudofunctoriality isomorphisms corresponding to the identities $\pi_{13} \circ \Delta=\Delta \circ \pi_{1}$ and $\pi_{12} \circ \Delta=\pi_{23} \circ \Delta=\mathrm{Id}$.

### 3.2. Non-compact case

In practice, one often has to deal with cases when neither $X_{1}$ nor $X_{2}$ are proper. A common way to deal with such situations is to restrict to the full subcategories of objects with proper support. However, with a bit of care it is still possible to work in full generality.

So let $X_{1}$ and $X_{2}$ be any two separable schemes of finite type over $k$, not necessarily proper, and let $E$ be a perfect object of $D\left(X_{1} \times X_{2}\right)$. We want to write down the left adjoint $\Phi_{E}^{\text {lad } j}$ of $\Phi_{E}=\pi_{2 *}\left(E \otimes \pi_{1}^{*}(-)\right)$, but since $\pi_{1}$ is not necessarily a proper morphism, the left adjoint to $\pi_{1}^{*}$ does not necessarily exist.

To construct $\Phi_{E}^{\text {ladj }}$, we compactify $X_{2}$ - that is, we choose an open immersion $j: X_{2} \hookrightarrow \bar{X}_{2}$ with $\bar{X}_{2}$ proper over $k$, cf. [16], or [23] for a more modern exposition. We shall abuse the notation by using $j$ to also denote immersions $X_{1} \times X_{2} \rightarrow X_{1} \times \bar{X}_{2}$ and $X_{1} \times X_{2} \times X_{1} \rightarrow X_{1} \times \bar{X}_{2} \times X_{1}$ where it causes no confusion. For any such compactified product space we shall denote by $\bar{\pi}_{i}$ and $\bar{\pi}_{i j}$ projections onto corresponding factors. Also, write $\bar{E}$ for $j_{*} E$.

We have the following commutative diagram:

Lemma 3.3. Let $E \in D_{\text {perf }}\left(X_{1} \times X_{2}\right)$. There is an isomorphism of functors $D_{q c}\left(X_{1}\right) \rightarrow$ $D_{q c}\left(\bar{X}_{2}\right)$

$$
\begin{equation*}
\Phi_{\bar{E}} \xrightarrow{\sim} j_{*} \Phi_{E} . \tag{3.36}
\end{equation*}
$$

Its left adjoint with respect to $j_{*}$ is an isomorphism of functors $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{2}\right)$

$$
\begin{equation*}
j^{*} \Phi_{\bar{E}} \xrightarrow{\sim} \Phi_{E} . \tag{3.37}
\end{equation*}
$$

Proof. For the first claim, we set (3.36) to be

$$
\begin{aligned}
& \Phi_{\bar{E}}=\bar{\pi}_{2 *}\left(j_{*} E \otimes \bar{\pi}_{1}^{*}(-)\right) \\
& \xrightarrow{\alpha_{j}} \bar{\pi}_{2 *} j_{*}\left(E \otimes j^{*} \bar{\pi}_{1}^{*}(-)\right) \xrightarrow{\eta_{j, \pi_{2} \circ \eta_{\bar{\pi}_{2}, j}^{-1} \circ \zeta \bar{\pi}_{1}, j}} j_{*} \pi_{2 *}\left(E \otimes \pi_{1}^{*}(-)\right)=j_{*} \Phi_{E} .
\end{aligned}
$$

For the second claim: (3.37) is the composition of the image of (3.36) under $j^{*}$ with the adjunction counit $\gamma_{j}: j^{*} j_{*} \Phi_{E} \rightarrow \Phi_{E}$. And $\gamma_{j}$ is an isomorphism since $j$ is an open immersion [5, Prop. 9.4.2].

We now need the following key lemma:
Lemma 3.4. Let $X$ be a concentrated scheme and let $U \xrightarrow{j} X$ be an open immersion. Let $D_{q c}^{j}(X)$ be the full subcategory of $D_{q c}(X)$ formed by the images of the objects of $D_{q c}(U)$ under $j_{*}$. Let $D^{j}(X)$ and $D_{\text {perf }}^{j}(X)$ be the full subcategories of $D_{q c}^{j}(X)$ consisting of complexes with bounded and coherent cohomology and of perfect complexes. Then:
(1) Functors $j_{*}$ and $j^{*}$ restrict to mutually inverse equivalences between $D_{q c}^{j}(X)$ and $D_{q c}(U)$.
(2) For any $A \in D_{q c}(X)$ functors $A \otimes(-)$ and $\mathbf{R} \mathcal{H o m}_{X}(A,-)$ restrict to functors $D_{q c}^{j}(X) \rightarrow$ $D_{q c}^{j}(X)$ and are identified by $j^{*}$ with $j^{*} A \otimes(-)$ and $\mathbf{R} \mathcal{H o m}_{U}\left(j^{*} A,-\right)$.
(3) Let $X^{\prime} \xrightarrow{f} X$ be a concentrated map and consider the following base change diagram:

The functors $f_{*}$ and $f^{*}$ restrict to functors between $D_{q c}^{j^{\prime}}\left(X^{\prime}\right)$ and $D_{q c}^{j}(X)$ and are identified by the equivalences $j^{*}$ and $j^{\prime *}$ with functors $g_{*}$ and $g^{*}$.
(4) Let $X$ be noetherian. The equivalence $j^{*}$ identifies $D^{j}(X)$ and $D_{p e r f}^{j}(X)$ with $D^{c l s}(U)$ and $D_{\text {perf }}^{\text {cls }}(U)$, the full subcategories of $D(U)$ and $D_{\text {perf }}(U)$ consisting of objects whose support is closed in $X$.
(5) Let $X$ be noetherian. For any $A \in D_{q c}^{+}(X)$ functor $\mathbf{R} \mathcal{H o m}_{X}(-, A)$ restricts to a functor $D^{j}(X) \rightarrow D_{q c}^{j}(X)$ and the equivalence $j^{*}$ identifies it with $\mathbf{R} \mathcal{H o m}_{U}\left(-, j^{*} A\right)$.
Proof. Since $j$ is an open immersion, the adjunction co-unit $j^{*} j_{*} \xrightarrow{\gamma_{j}}$ Id is an isomorphism. It follows that $j_{*}$ is fully faithful, so its restriction to a functor $D_{q c}(U) \rightarrow D_{j}(X)$ is tautologically an equivalence. It also follows that $j^{*}$ is the inverse equivalence to $j_{*}$. This settles claim (1).

For claim (2), it follows from the projection formula isomorphism

$$
A \otimes j_{*}(-) \xrightarrow{\alpha_{j}} j_{*}\left(j^{*} A \otimes-\right)
$$

that $A \otimes(-)$ restricts to a functor $D^{j}(X) \rightarrow D_{j}(X)$ and that this restriction is identified by $j^{*}$ with

$$
j^{*} A \otimes(-): D_{q c}(U) \rightarrow D_{q c}(U)
$$

The assertion for the functor $\mathbf{R} \mathcal{H o m}_{X}(A,-)$ follows similarly from the sheafified adjunction isomorphism

$$
j_{*} \mathbf{R} \mathcal{H o m}_{U}\left(j^{*} A,-\right) \xrightarrow{\tau_{j}} \mathbf{R} \mathcal{H o m}_{X}\left(A, j_{*}(-)\right) .
$$

The claim (3) follows in the same way from the pseudo-functoriality isomorphism $f_{*} j_{*}^{\prime} \xrightarrow{\eta_{j, g} \circ \eta_{f, j^{\prime}}^{-1}} j_{*} g_{*}$ and the flat base change isomorphism $f^{*} j_{*} \xrightarrow{\mu_{\sigma}} j_{*}^{\prime} g^{*}$.

For claim (4), first note that $j$ is an open immersion of noetherian schemes and thus perfect. Now let $A$ be any object of $D^{j}(X)$ and let $B=j^{*} A$ so that $A=j_{*} B$. Since $j$ is perfect, $B$ lies in $D(U)$. We have $\operatorname{Supp}_{U} B=\left(\operatorname{Supp}_{X} A\right) \cap U$ and we need to check that this set is closed in $X$. Since $A \in D(X)$, we know that $\operatorname{Supp}_{X} A$ is closed in $X$ and any point $p \in X$ lies in $\operatorname{Supp}_{X} A$ if and only if $\iota_{p}^{*} A \neq 0$, where $\iota_{p}$ is the inclusion map. On the other hand, for any $p \in X \backslash U$ we have $\iota_{p}^{*} A=\iota_{p}^{*} j_{*} B=0$ by the base change formula. Hence $\operatorname{Supp}_{X} A \subset U, \operatorname{so~}^{\operatorname{Supp}}{ }_{U} B=\operatorname{Supp}_{X} A$ and hence closed in $X$. We conclude that $B \in D^{c l s}(U)$ as required.

Conversely, let $B \in D^{c l s}(U)$ and let $A=j_{*} B$. Since $B \in D(U)$ we can find a fat enough closed subscheme $Z \xrightarrow{k} U$ with the underlying set $\operatorname{Supp}_{U} B$ to ensure that $B \simeq k_{*} C$ for some $C \in D(Z)$. Since $\operatorname{Supp}_{U} B$ is closed in $X$, the composite map $Z \xrightarrow{j o k} X$ is a closed immersion. We conclude that $A=j_{*} B \simeq j_{*} k_{*} C \simeq(j \circ k)_{*} C$ lies in $D(X)$, as required.

We have now shown that $j^{*}$ identifies $D^{j}(X)$ with $D^{c l s}(U)$. Finally, any inverse image functor takes perfect complexes to perfect complexes [9, Cor. 4.19.1], therefore $j^{*}$ takes $D_{p e r f}^{j}(X)$ to $D_{\text {perf }}^{c l s}(U)$. Conversely, let $A$ be a perfect object in $D^{c l s}(U)$, then it is, in particular, of finite Tor-dimension. As $j$ is perfect, $j_{*} A$ is also of finite Tor-dimension [8, Cor. 3.7.2]. Since we already know that $j_{*} A \in D(X)$, we conclude that $j_{*} A$ is perfect. Thus $j^{*}$ identifies $D_{\text {perf }}^{j}(X)$ with $D_{p e r f}^{c l s}(U)$. This settles claim (4).

For claim (5), take any $B \in D^{j}(X)$. Then, as before, we can find a closed immersion $Z \xrightarrow{k} U$ and an object $C \in D(Z)$ such that $B=(j \circ k)_{*} C$. We then have a functorial isomorphism

$$
\mathbf{R} \mathcal{H o m}_{X}\left((j \circ k)_{*} C, A\right) \xrightarrow{\eta_{j, k} \circ \delta_{j o k}} j_{*} k_{*} \mathbf{R} \mathcal{H o m}_{Z}\left(C,(j \circ k)^{!} A\right)
$$

which shows that functor $\mathbf{R} \mathcal{H o m}_{X}(-, A)$ restricts to a functor $D^{j}(X) \rightarrow D_{q c}^{j}(X)$. Finally, this restriction is identified by $j^{*}$ with $\mathbf{R} \mathcal{H o m}_{U}\left(-, j^{*} A\right)$ because $j$ is an open immersion and hence the natural morphism

$$
j^{*} \mathbf{R} \mathcal{H o m}_{X}(B, A) \rightarrow \mathbf{R} \mathcal{H o m}_{X}\left(j^{*} B, j^{*} A\right)
$$

is an isomorphism [3, Lemma 2.1.7].

## Corollary 3.5. The Fourier-Mukai transform

$$
\Phi_{E}: \quad D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{2}\right)
$$

has a left adjoint $\Phi_{E}^{\text {ladj }}$, and this adjoint is isomorphic to the Fourier-Mukai transform

$$
\Psi_{E^{\vee} \otimes \pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right)}: \quad D_{q c}\left(X_{2}\right) \rightarrow D_{q c}\left(X_{1}\right)
$$

If $\operatorname{Supp}_{X_{1} \times X_{2}} E$ is proper over $X_{1}$ and $X_{2}$, then $\Phi_{E}$ and $\Phi_{E}^{\text {ladj }}$ restrict to functors between $D\left(X_{1}\right)$ and $D\left(X_{2}\right)$.

Proof. We only prove the first claim, as the assertion about the restriction to $D\left(X_{1}\right)$ and $D\left(X_{2}\right)$ is standard. By Lemma 3.3 functor $\Phi_{\bar{E}}$ is isomorphic to $j_{*} \Phi_{E}$. Hence it restricts to a functor $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}^{j}\left(\bar{X}_{2}\right)$. Thus, by the same lemma, $\Phi_{E}$ is isomorphic to the composition

$$
D_{q c}\left(X_{1}\right) \xrightarrow{\Phi_{\bar{E}}} D_{q c}^{j}\left(\bar{X}_{2}\right) \xrightarrow{j^{*}} D_{q c}\left(X_{2}\right) .
$$

By Lemma 3.4(1) the functor $D_{q c}^{j}\left(\bar{X}_{2}\right) \xrightarrow{j^{*}} D_{q c}\left(X_{2}\right)$ is an equivalence whose inverse is the functor $j_{*}$. Therefore $\Phi_{E}$ has a left adjoint $\Phi_{E}^{\text {lad } j}$ isomorphic to $\Phi_{\bar{E}}^{l a d j} j_{*}$, that is to

$$
\bar{\pi}_{1 *}\left(\bar{E}^{\vee} \otimes \bar{\pi}_{1}^{!}\left(\mathcal{O}_{X_{1}}\right) \otimes \bar{\pi}_{2}^{*} j_{*}(-)\right)
$$

By Lemma 3.4(2)-(5) this is further isomorphic to

$$
\bar{\pi}_{1 *} j_{*}\left(E^{\vee} \otimes j^{*} \bar{\pi}_{1}^{!}\left(\mathcal{O}_{X_{1}}\right) \otimes \pi_{2}^{*}(-)\right)
$$

Since $\pi_{1}=\bar{\pi}_{1} \circ j$, the claim now follows by the pseudofunctoriality of $(-)_{*}$ and $(-)^{!}$.
The isomorphism $\Phi_{\bar{E}} \xrightarrow{(3.36)} j_{*} \Phi_{E}$ of functors induces the unique isomorphism

$$
\begin{equation*}
\Phi_{\bar{E}}^{\text {ladj }} \xrightarrow{\sim} \Phi_{E}^{\text {lad j }} j^{*} \tag{3.39}
\end{equation*}
$$

of their left adjoints $D_{q c}\left(\bar{X}_{2}\right) \rightarrow D_{q c}\left(X_{1}\right)$ which makes the diagram

of functors $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{1}\right)$ commute. Therefore the adjunction co-unit $\Phi_{E}^{l a d j} \Phi_{E} \xrightarrow{\gamma_{E}} \mathrm{Id}$ is isomorphic to the adjunction co-unit $\Phi_{\bar{E}}^{\text {ladj }} \Phi_{\bar{E}} \xrightarrow{\gamma_{\bar{E}}}$ Id. The standard Fourier-Mukai kernel of $\Phi_{\bar{E}}^{\text {ladj }} \Phi_{\bar{E}}$ is

$$
\bar{Q}=\bar{\pi}_{13 *}\left(\bar{\pi}_{12}^{*} \bar{E} \otimes \bar{\pi}_{23}^{*} \bar{E}^{\vee} \otimes \bar{\pi}_{23}^{*} \bar{\pi}_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)
$$

and Theorem 3.1 supplies us with the morphism $\bar{Q} \rightarrow \Delta_{*} \mathcal{O}_{X_{1}}$ which induces $\Phi_{\bar{E}}^{\text {ladj }} \Phi_{\bar{E}} \xrightarrow{\gamma_{\bar{E}}}$ Id. We obtain:

Proposition 3.6. The adjunction counit $\gamma_{E}: \Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id is isomorphic to the morphism of Fourier-Mukai transforms $D_{q c}\left(X_{1}\right) \rightarrow D_{q c}\left(X_{1}\right)$ induced by the morphism $\bar{Q} \rightarrow \Delta_{*} \mathcal{O}_{X_{1}}$ of Theorem 3.1.

As a non-essential aside, the standard Fourier-Mukai kernel of $\Phi_{E}^{l a d j} \Phi_{E}$ itself is

$$
Q=\pi_{13 *}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*} E^{\vee} \otimes \pi_{23}^{*} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)
$$

The functors $\Phi_{E}^{l a d j} \Phi_{E}$ and $\Phi_{\bar{E}}^{l a d j} \Phi_{\bar{E}}$ are isomorphic, but it does not a priori mean that $Q$ and $\bar{Q}$ are isomorphic. However, it is easy to check that they are - we leave the details as an exercise for the reader.

## 4. An alternative description for the pushforward kernels

Whenever $E$ is direct image of an object from the derived category of some subscheme of $X_{1} \times X_{2}$ the decomposition of the morphism $Q \rightarrow \mathcal{O}_{\Delta}$ given in Theorem 3.1 is usually very
poorly suited for computing cones. We first illustrate this in Section 4.1 with an example where $E$ is the structure sheaf of a global complete intersection subscheme and so everything can be worked out explicitly using Koszul-type resolutions. For a general closed subscheme of $X_{1} \times X_{2}$ such a resolution does not exist and a different approach is needed. But with an insight obtained from Section 4.1 we set up some general machinery in Sections 4.2 and 4.3 which we then apply in Section 4.4 to obtain a better description of the morphism $Q \rightarrow \mathcal{O}_{\Delta}$ for $E$ being a pushforward from an arbitrary closed subscheme.

### 4.1. The global complete intersection example

Let $X_{1}$ and $X_{2}$ be a pair of smooth varieties over $k$ with $X_{2}$ proper. Let $\mathcal{N}$ be a vector bundle of rank $d$ on $X_{1} \times X_{2}$ and let $s$ be a regular global section of $\mathcal{N}$. Let $Z$ be the zero-locus of $s$ in $X_{1} \times X_{2}$, it is a closed subscheme of codimension $d$ and normal bundle $\left.\mathcal{N}\right|_{Z}$. Let $Z \times X_{1}$ and $X_{1} \times Z$ be Tor-independent in $X_{1} \times X_{2} \times X_{1}$, i.e. the derived tensor product $\mathcal{O}_{Z \times X_{1}} \otimes \mathcal{O}_{X_{1} \times Z}$ is $\mathcal{O}_{Z^{\prime}}$ where $Z^{\prime}=\left(Z \times X_{1}\right) \cap\left(X_{1} \times Z\right)$. We can rewrite the first two morphisms in the decomposition of Theorem 3.1 for $E=\mathcal{O}_{Z}$ as the images under $\pi_{13 *}\left(-\otimes \pi_{23}^{*} \pi_{2}^{!} \mathcal{O}_{X_{1}}\right)$ of the following morphism in $D_{q c}\left(X_{1} \times X_{2} \times X_{1}\right)$ :

$$
\begin{equation*}
\pi_{12}^{*} \mathcal{O}_{Z} \otimes \pi_{23}^{*} \mathcal{O}_{Z}^{\vee} \xrightarrow{\beta_{\Delta}} \Delta_{*}\left(\mathcal{O}_{Z} \otimes \mathcal{O}_{Z}^{\vee}\right) \xrightarrow{\Delta_{*} \mathrm{ev}_{\mathcal{O}_{Z}}} \Delta_{*} \mathcal{O}_{X_{1} \times X_{2}} \tag{4.1}
\end{equation*}
$$

Note that by the flat base change for the twisted inverse image pseudofunctor (see Section 2.2) the object $\pi_{1}^{!} \mathcal{O}_{X_{1}}$ is just the shifted line bundle $\pi_{2}^{*} \omega_{X_{2}}\left[\operatorname{dim} X_{2}\right]$.

The structure sheaf $\mathcal{O}_{Z}$ has a global Koszul resolution on $X_{1} \times X_{2}$

$$
\begin{equation*}
\wedge^{d} \mathcal{N}^{\vee} \rightarrow \wedge^{d-1} \mathcal{N}^{\vee} \rightarrow \cdots \rightarrow \mathcal{N}^{\vee} \rightarrow \mathcal{O}_{X_{1} \times X_{2}} \tag{4.2}
\end{equation*}
$$

whose differential maps are defined in the usual way by valuations at $s$. In particular, they all vanish along $Z$. Dualizing the Koszul complex, we see immediately that $\mathcal{O}_{Z}^{\vee}$ is isomorphic to $\mathcal{O}_{Z} \otimes \wedge^{d} \mathcal{N}[-d]$ in $D\left(X_{1} \times X_{2}\right)$.

We have $\pi_{12}^{-1}(Z)=Z \times X_{1}$ and $\pi_{23}^{-1}(Z)=X_{1} \times Z$. So $\pi_{12}^{*} \mathcal{O}_{Z} \simeq O_{Z \times X_{1}}$, while $\pi_{23}^{*} \mathcal{O}_{Z}^{\vee}=\mathcal{O}_{X_{1} \times Z} \otimes \pi_{23}^{*}\left(\wedge^{d} \mathcal{N}\right)[-d]$. Thus $\pi_{12}^{*} \mathcal{O}_{Z} \otimes \pi_{23}^{*} \mathcal{O}_{Z}^{\vee}$, the first term in (4.1), equals $\mathcal{O}_{Z \times X_{1}} \otimes \mathcal{O}_{X_{1} \times Z} \otimes \pi_{23}^{*}\left(\wedge^{d} \mathcal{N}\right)[-d]$. By assumption $Z \times X_{1}$ and $X_{1} \times Z$ are Tor-independent, and $\pi_{23}^{*} \wedge^{d} \mathcal{N}[-d]$ is a line bundle, so we conclude that the first term in (4.1) equals $\left.\left(\pi_{23}^{*} \wedge^{d} \mathcal{N}\right)\right|_{Z^{\prime}}[-d]$.

On the other hand, $\Delta_{*}\left(\mathcal{O}_{Z} \otimes \mathcal{O}_{Z}^{\vee}\right)$, the second term in (4.1), is isomorphic to the image under $\Delta_{*}$ of the restriction of the dual of the complex (4.2) to $Z$. Since all the differentials vanish along $Z$, this equals

$$
\begin{equation*}
\Delta_{*}\left(\left.\left.\mathcal{O}_{Z} \xrightarrow{0} \mathcal{N}\right|_{Z} \xrightarrow{0} \cdots \xrightarrow{0} \wedge^{d} \mathcal{N}\right|_{Z}\right)=\bigoplus_{i=0}^{d} \wedge^{i} \mathcal{N} \mid \Delta(Z)[-i], \tag{4.3}
\end{equation*}
$$

where $\Delta(Z)$ is the image of $Z$ under $X_{1} \times X_{2} \xrightarrow{\Delta} X_{1} \times X_{2} \times X_{1}$.
Thus the decomposition (4.1) is not practical from the point of view of computing cones. Its first map goes from $\left.\left(\pi_{23}^{*} \wedge^{d} \mathcal{N}\right)\right|_{Z^{\prime}}[-d]$, a single sheaf sitting in the degree $d$, to $\left.\bigoplus_{i=0}^{d} \wedge^{i} \mathcal{N}\right|_{\Delta(Z)}[-i]$, a huge complex with non-zero cohomologies in all degrees from 0 to $d$. Its second map goes from this huge complex to $\mathcal{O}_{\Delta\left(X_{1} \times X_{2}\right)}$, a single sheaf sitting in the degree 0 .

We get two huge cones with non-zero cohomologies in all degrees from 0 to $d$ which almost entirely annihilate each other when we take the cone of the map between them.

In the rest of this section we prove, in a much more general setting, that there exists a more economical decomposition than (4.1). Applied to the case at hand, our result will tell us that the decomposition (4.1) filters through the summand $\left.\wedge^{d} \mathcal{N}\right|_{\Delta(Z)}[-d]$ of $\left.\bigoplus_{i=0}^{d} \wedge^{i} \mathcal{N}\right|_{\Delta(Z)}[-i]$, and can be written simply as:

$$
\begin{align*}
& \left.\left.\left(\pi_{23}^{*} \wedge^{d} \mathcal{N}\right)\right|_{Z^{\prime}}[-d] \xrightarrow{Z^{\prime} \rightarrow \Delta(Z)} \wedge^{d} \mathcal{N}\right|_{\Delta(Z)}[-d] \\
& \quad \simeq \Delta_{*} \mathcal{O}_{Z}^{\vee} \xrightarrow{\Delta_{*}\left(\mathcal{O}_{\left.X_{1} \times X_{2} \rightarrow \mathcal{O}_{Z}\right)^{\vee}} \Delta_{*} \mathcal{O}_{X_{1} \times X_{2}} .\right.} . \tag{4.4}
\end{align*}
$$

The cones of these two maps are small compared to those in (4.1) and easy to compute.

### 4.2. A decomposition of the evaluation map

Let $Y \xrightarrow{f} X$ be a map of concentrated schemes.
Proposition 4.1. For any $E \in D\left(\mathcal{O}_{Y}-\mathbf{M o d}\right)$ the following diagram commutes

Proof. Let us show that the right adjoint of (4.5) with respect to $f_{*} E \otimes(-)$ commutes. The result in [13, Prop. 3.2.4(ii)] tells what is the right adjoint of $f_{*} E \otimes f_{*}(-) \xrightarrow{\kappa_{f}} f_{*}(E \otimes-)$ with respect to $f_{*} E \otimes(-)$. It follows immediately that the right adjoint of

$$
f_{*} E \otimes f_{*} \mathbf{R} \mathcal{H o m}(E,-) \xrightarrow{\kappa_{f}} f_{*}(E \otimes \mathbf{R} \mathcal{H o m}(E,-)) \xrightarrow{\operatorname{ev}_{E}} f_{*}(-)
$$

with respect to $f_{*} E \otimes(-)$ is

$$
f_{*} \mathbf{R} \mathcal{H o m}(E,-) \xrightarrow{\gamma_{f}} f_{*} \mathbf{R} \mathcal{H o m}\left(f^{*} f_{*} E,-\right) \xrightarrow{\tau_{f}} \mathbf{R} \mathcal{H o m}\left(f_{*} E, f_{*}-\right) .
$$

Therefore the right adjoint of the composition $\epsilon_{f} \circ \mathrm{ev}_{E} \circ \kappa_{f}$ in (4.5) is

$$
\begin{aligned}
f_{*} \mathbf{R} \mathcal{H o m}\left(E, f^{\times} \mathcal{O}_{X}\right) \xrightarrow{\gamma_{f}} f_{*} \mathbf{R} \mathcal{H o m}\left(f^{*} f_{*} E, f^{\times} \mathcal{O}_{X}\right) \\
\xrightarrow{\tau_{f}} \mathbf{R} \operatorname{Hom}\left(f_{*} E, f_{*} f^{\times} \mathcal{O}_{X}\right) \xrightarrow{\epsilon_{f}} \mathbf{R} \mathcal{H o m}\left(f_{*} E, \mathcal{O}_{X}\right) .
\end{aligned}
$$

By definition this is just the sheafified Grothendieck duality morphism

$$
f_{*} \mathbf{R} \mathcal{H o m}\left(E, f^{\times} \mathcal{O}_{X}\right) \xrightarrow{\delta_{f}} \mathbf{R} \mathcal{H o m}\left(f_{*} E, \mathcal{O}_{X}\right) .
$$

So is clearly the right adjoint of the composition $\mathrm{ev}_{f_{*} E} \circ\left(\operatorname{Id} \otimes \delta_{f}\right)$ in (4.5). The claim follows.

### 4.3. Künneth maps and the base change

Let $Y \xrightarrow{f} X$ be a map of concentrated schemes. Morphism $\kappa_{f}: f_{*}(-) \otimes f_{*}(-) \rightarrow f_{*}(-\otimes-)$ can be interpreted as the Künneth map of the commutative square:

We recall the basics on the Künneth map, cf. [13, Section 3.10]:
Definition 4.2. Let

be a commutative square of concentrated schemes. Setting $h=f_{1} \circ g_{1}=f_{2} \circ g_{2}$ define the Künneth map to be the bifunctorial morphism

$$
\begin{equation*}
\kappa_{\sigma}: f_{1 *}\left(A_{1}\right) \otimes f_{2 *}\left(A_{2}\right) \rightarrow h_{*}\left(g_{1}^{*}\left(A_{1}\right) \otimes g_{2}^{*}\left(A_{2}\right)\right) \quad A_{i} \in D\left(Y_{i}\right) \tag{4.8}
\end{equation*}
$$

which is the composition

$$
\begin{align*}
& f_{1 *}\left(A_{1}\right) \otimes f_{2 *}\left(A_{2}\right) \xrightarrow{\beta_{h}} h_{*} h^{*}\left(f_{1 *}\left(A_{1}\right) \otimes f_{2 *}\left(A_{2}\right)\right) \\
& \xrightarrow{\nu_{h}} h_{*}\left(h^{*} f_{1 *}\left(A_{1}\right) \otimes h^{*} f_{2 *}\left(A_{2}\right)\right) \xrightarrow{\zeta_{f_{1}, g_{1}}^{-1} \otimes \zeta_{f_{2}, g_{2}}^{-1}} \\
& h_{*}\left(g_{1}^{*} f_{1}^{*} f_{1 *}\left(A_{1}\right) \otimes g_{2}^{*} f_{2}^{*} f_{2 *}\left(A_{2}\right)\right) \xrightarrow{\gamma_{f_{1}} \otimes \gamma_{f_{2}}} h_{*}\left(g_{1}^{*}\left(A_{1}\right) \otimes g_{2}^{*}\left(A_{2}\right)\right) \tag{4.9}
\end{align*}
$$

with $\beta_{h}$ being the adjunction unit $\operatorname{Id}_{X} \rightarrow h_{*} h^{*}$ and $\gamma_{f_{i}}$ being the adjunction counits $f_{i}^{*} f_{i *} \rightarrow$ $\operatorname{Id}_{Y_{i}}$.

A commutative square is called Künneth-independent if its Künneth map is a bifunctorial isomorphism. For fiber squares of concentrated schemes this notion of independence is equivalent to several others:

Proposition 4.3 ([13], Theorem 3.10.3). Let

be a fiber square of concentrated schemes, then the following are equivalent:
(1) $\sigma$ is independent, i.e. the base change map $\mu_{\sigma}: f_{1}^{*} f_{2 *} \rightarrow g_{1 *} g_{2}^{*}$ is a functorial isomorphism.
(2) $\sigma$ is Künneth-independent.
(3) $\sigma$ is Tor-independent, i.e. for any pair of points $y_{1} \in Y_{1}$ and $y_{2} \in Y_{2}$ with $f_{1}\left(y_{1}\right)=f_{2}\left(y_{2}\right)=$ $x \in X$ we have

$$
\begin{equation*}
\operatorname{Tor}_{\mathcal{O}_{X, x}}^{i}\left(\mathcal{O}_{Y_{1}, y_{1}}, \mathcal{O}_{Y_{2}, y_{2}}\right)=0 \quad \text { for all } i>0 \tag{4.11}
\end{equation*}
$$

What we saw in Section 4.1 is a special case of a very general base change statement for Künneth maps:

Proposition 4.4. Let

be a commutative square of concentrated schemes and set $h=f_{1} \circ g_{1}=f_{2} \circ g_{2}$. Let $u: X^{\prime} \rightarrow X$ be any morphism and let $\sigma^{\prime}$ be the fiber product of $\sigma$ with $X^{\prime}$ over $X$, that is the outer square ( $Z^{\prime}, Y_{1}^{\prime}, Y_{2}^{\prime}, X^{\prime}$ ) in the commutative diagram

where $Y_{i}^{\prime}=Y_{i} \times_{X, f_{i}, u} X^{\prime}, Z^{\prime}=Z \times_{X, h, u} X^{\prime}=Z \times_{Y_{i}, g_{i}, u} Y_{i}^{\prime}$ and the four squares between $\sigma^{\prime}$ and $\sigma$ are the corresponding fiber squares. Let also $h^{\prime}=f_{1}^{\prime} \circ g_{1}^{\prime}=f_{2}^{\prime} \circ g_{2}^{\prime}$. Finally, to unburden the notation, write

- $\eta_{f_{1}}$ for the pseudofunctoriality isomorphism $f_{1 *} u_{*} \xrightarrow{\eta_{u, f_{1}^{\prime}} \circ \eta_{f_{1}, u}^{-1}} u_{*} f_{1 *}^{\prime}$.
- $\zeta_{f_{1}}$ for the pseudofunctoriality isomorphism $u^{*} f_{1}^{*} \xrightarrow{\zeta_{u, f_{1}^{\prime}}^{-1} \circ \zeta_{f_{1}, u}} f_{1}^{\prime *} u^{*}$
- $\mu_{f_{1}}$ for the base change map $u^{*} f_{1 *} \rightarrow f_{1 *}^{\prime} u^{*}$ of the corresponding fiber square. and analogously for $f_{2}, g_{1}, g_{2}$ and $h$.

Then for any objects $A_{1} \in D\left(Y_{1}\right)$ and $A_{2} \in D\left(Y_{2}\right)$ :
(1) The following diagram commutes in $D\left(X^{\prime}\right)$ :

$$
\begin{gather*}
u^{*}\left(f_{1 *}\left(A_{1}\right) \otimes f_{2 *}\left(A_{2}\right)\right) \xrightarrow{u^{*} \kappa_{\sigma}} u^{*} h_{*}\left(g_{1}^{*}\left(A_{1}\right) \otimes g_{2}^{*}\left(A_{2}\right)\right) \\
\left(\mu_{f_{1}} \otimes \mu_{f_{2}}\right) \circ v_{u}  \tag{4.14}\\
\downarrow \\
f_{1 *}^{\prime}\left(u^{*} A_{1}\right) \otimes f_{2 *}^{\prime}\left(u^{*} A_{2}\right) \xrightarrow[\kappa_{\sigma^{\prime}}]{\longrightarrow} h_{*}^{\prime}\left(g_{1}^{\prime *}\left(\left(u^{*} A_{1}\right) \otimes \zeta_{g 2}\right) \circ v_{u}\right) \circ \mu_{h} \\
\left.{ }_{2}^{*}\left(u^{*} A_{2}\right)\right)
\end{gather*}
$$

(2) The following diagram commutes in $D(X)$ :

$$
\begin{align*}
& f_{1 *}\left(A_{1}\right) \otimes f_{2 *}\left(A_{2}\right) \xrightarrow{\kappa_{\sigma}} h_{*}\left(g_{1}^{*}\left(A_{1}\right) \otimes g_{2}^{*}\left(A_{2}\right)\right) \\
& \beta_{u} \downarrow \quad \downarrow^{h_{*} \beta_{u}} \\
& u_{*} u^{*}\left(f_{1 *}\left(A_{1}\right) \otimes f_{2 *}\left(A_{2}\right)\right)  \tag{4.15}\\
& u_{*}\left(\left(\mu_{f_{1}} \otimes \mu_{f_{2}}\right) \circ v_{u}\right) \downarrow \\
& u_{*}\left(f_{1 *}^{\prime}\left(u^{*} A_{1}\right) \otimes f_{2 *}^{\prime}\left(u^{*} A_{2}\right)\right) \xrightarrow[u_{*} \kappa_{\sigma^{\prime}}]{ } u_{*} h_{*}^{\prime}\left(g_{1}^{*}\left(u^{*} A_{1}\right) \otimes g_{2}^{*}\left(u^{*} A_{2}\right)\right)
\end{align*}
$$

Proof. By definition, the right adjoint of the base change map $u^{*} h_{*} \xrightarrow{\mu_{h}} h_{*}^{\prime} u^{*}$ with respect to $u^{*}$ is the composition $h_{*} \xrightarrow{h_{*} \beta_{u}} h_{*} u_{*} u^{*} \xrightarrow{\eta_{h}} u_{*} h_{*}^{\prime} u^{*}$. It follows that the diagram (4.15) is the right adjoint of the diagram (4.14) with respect to $u_{*}$, so we only need to prove that (4.15) commutes.

Let $B \xrightarrow{m} h_{*} u_{*} C$ be any morphism between some $B \in D(X)$ and some $C \in D\left(Z^{\prime}\right)$. Let $l$ be the left adjoint $u^{*} h^{*} B \rightarrow C$ of $m$ with respect to $h_{*} u_{*}$. By compatibility of the inverse image/direct image adjunction with pseudofunctoriality, the left adjoint with respect to $u_{*} h_{*}^{\prime}$ of the composition $B \xrightarrow{m} h_{*} u_{*} C \xrightarrow{\eta_{h}} u_{*} h_{*}^{\prime} C$ is the composition $h^{*} u^{*} B \xrightarrow{\zeta_{h}^{-1}} u^{*} h^{*} B \xrightarrow{l} C$. Hence the left adjoint with respect to $u_{*} h_{*}^{\prime}$ of the upper-right half

$$
\begin{aligned}
& f_{1 *} A_{1} \otimes f_{2 *} A_{2} \xrightarrow{\kappa_{\sigma}} h_{*}\left(g_{1}^{*} A_{1} \otimes g_{2}^{*} A_{2}\right) \xrightarrow{\nu_{u} \circ h_{*} \beta_{u}} h_{*} u_{*}\left(u^{*} g_{1}^{*} A_{1} \otimes u^{*} g_{2}^{*} A_{2}\right) \\
& \xrightarrow{\eta_{\hbar} \circ h_{*} u_{*}\left(\zeta_{g_{1}} \otimes \zeta_{g_{2}}\right)} u_{*} h_{*}^{\prime}\left(g_{1}^{\prime *} u^{*} A_{1} \otimes g_{2}^{*} u^{*} A_{2}\right)
\end{aligned}
$$

of (4.15) is the composition of $h^{*} u^{*}\left(f_{1 *} A_{1} \otimes f_{2 *} A_{2}\right) \xrightarrow{\zeta_{h}^{-1}} u^{*} h^{*}\left(f_{1 *} A_{1} \otimes f_{2 *} A_{2}\right)$ with the left adjoint of

$$
\begin{aligned}
& f_{1 *} A_{1} \otimes f_{2 *} A_{2} \xrightarrow{\kappa_{\sigma}} h_{*}\left(g_{1}^{*} A_{1} \otimes g_{2}^{*} A_{2}\right) \xrightarrow{\nu_{u} \circ h_{*} \beta_{u}} h_{*} u_{*}\left(u^{*} g_{1}^{*} A_{1} \otimes u^{*} g_{2}^{*} A_{2}\right) \\
& \xrightarrow{h_{*} u_{*}\left(\zeta_{g_{1}} \otimes \zeta_{g_{2}}\right)} h_{*} u_{*}\left(g_{1}^{\prime *} u^{*} A_{1} \otimes g_{2}^{\prime *} u^{*} A_{2}\right)
\end{aligned}
$$

with respect to $h_{*} u_{*}$. Making use of the definition of $\kappa_{\sigma}$ in (4.9), this adjoint works out to be

$$
\begin{aligned}
& u^{*} h^{*}\left(\bigotimes_{i} f_{i} A_{i}\right) \xrightarrow{v_{u} \circ\left(\bigotimes_{i} u^{*} \zeta_{f_{i}, g_{i}}^{-1}\right) u^{*} \nu_{h}} \bigotimes_{i} u^{*} g_{i}^{*} f_{i}^{*} f_{i *} A_{i} \\
& \xrightarrow{\bigotimes_{i} u^{*} g_{i}^{*} \gamma_{f_{i}}} \bigotimes_{i} u^{*} g_{i}^{*} A_{i} \xrightarrow{\bigotimes_{i} \zeta_{g_{i}}} \bigotimes_{i} g_{i}^{* *} u^{*} A_{i} .
\end{aligned}
$$

Composing with $h^{*} u^{*}\left(f_{1 *} A_{1} \otimes f_{2 *} A_{2}\right) \xrightarrow{\eta_{h}^{-1}} u^{*} h^{*}\left(f_{1 *} A_{1} \otimes f_{2 *} A_{2}\right)$ and simplifying we see that the left adjoint of (4.15) with respect to $u_{*} h_{*}^{\prime}$ is

$$
\begin{gathered}
h^{\prime *} u^{*}\left(\bigotimes_{i} f_{i *} A_{i}\right) \xrightarrow{\left(\otimes_{i} \zeta_{f_{i}^{\prime}, g_{i}^{\prime}}^{-1}\right) \circ \nu_{h^{\prime}} h^{\prime *} v_{u}} \bigotimes_{i} g_{i}^{\prime *} f_{i}^{\prime *} u^{*} f_{i *} A_{i} \\
\xrightarrow{\otimes_{i} g_{i}^{\prime *} \zeta_{f_{i}}^{-1}} \bigotimes_{i} g_{i}^{\prime *} u^{*} f_{i}^{*} f_{i *} A_{i} \xrightarrow{\bigotimes_{i} g_{i}^{\prime *} u^{*} \gamma_{f_{i}}} \bigotimes_{i} g_{i}^{\prime *} u^{*} A_{i} .
\end{gathered}
$$

Similarly, the left adjoint of the lower-left half

$$
\begin{aligned}
& f_{1 *} A_{1} \otimes f_{2 *} A_{2} \xrightarrow{\beta_{u}} u_{*} u^{*}\left(f_{1 *} A_{1} \otimes f_{2 *} A_{2}\right) \xrightarrow{u_{*}\left(\otimes_{i} \mu_{f_{i}}\right) u_{*} v_{u}} u_{*}\left(f_{1 *}^{\prime} u^{*} A_{1} \otimes f_{2 *}^{\prime} u^{*} A_{2}\right) \\
& \xrightarrow{u_{*} \kappa_{\sigma^{\prime}}} u_{*} h_{*}^{\prime}\left(g_{1}^{\prime *} u^{*} A_{1} \otimes g_{2}^{\prime *} u^{*} A_{2}\right)
\end{aligned}
$$

of (4.15) with respect to $u_{*} h_{*}^{\prime}$ works out as

$$
\begin{aligned}
& h^{\prime *} u^{*}\left(\bigotimes_{i} f_{i *} A_{i}\right) \xrightarrow{\left(\otimes_{i} \zeta_{f_{i}^{\prime}, g_{i}^{\prime}}^{-1}\right) \stackrel{v_{h^{\prime}} h^{\prime *} v_{u}}{\longrightarrow} \bigotimes_{i} g_{i}^{\prime *} f_{i}^{* *} u^{*} f_{i *} A_{i}} \\
& \stackrel{\otimes_{i} g_{i}^{\prime *} f_{i}^{* *} \mu_{f_{i}}}{\longrightarrow} \bigotimes_{i} g_{i}^{\prime *} f_{i}^{\prime *} f_{i *}^{\prime} u^{*} A_{i} \xrightarrow{\otimes_{i} g_{i}^{\prime *} \gamma_{f_{i}^{\prime}}} \bigotimes_{i} g_{i}^{\prime *} u^{*} A_{i} .
\end{aligned}
$$

It therefore suffices to show that the following diagram commutes for $i=1,2$ and for all $A_{i} \in D\left(Y_{i}\right)$

$$
\begin{align*}
& f_{i}^{\prime *} u^{*} f_{i *} A_{i} \xrightarrow{g_{i}^{\prime *} \zeta_{f_{i}}^{-1}} u^{*} f_{i}^{*} f_{i *} A_{i} \\
& f_{i}^{\prime *} u_{f_{i}} \downarrow  \tag{4.16}\\
& f_{i}^{\prime *} f_{i *}^{\prime} u^{*} A_{i} \xrightarrow[\gamma_{f_{i}^{\prime}}]{\longrightarrow} u^{*} \gamma_{f_{i}} \\
& u^{*} A_{i} .
\end{align*}
$$

By definition of $\mu_{f_{i}}$ in (2.34) the right adjoint with respect to $f_{i}^{\prime *}$ of $f_{i}^{\prime *} u^{*} f_{i *} \xrightarrow{\zeta_{f_{i}}^{-1}}$ $u^{*} f_{i}^{*} f_{i *} \xrightarrow{u^{*} \gamma_{f_{i}}} u^{*}$ is precisely $u^{*} f_{i *} \xrightarrow{\mu_{f_{i}}} f_{i *}^{\prime} u^{*}$. So the right adjoint with respect to $f_{i}^{\prime *}$ of (4.16) is the diagram

which clearly commutes.

### 4.4. The adjunction counits for the pushforward Fourier-Mukai kernels

We can now apply the generalities of the previous two sections to obtain an alternative decomposition to that in Theorem 3.1 of the morphism of Fourier-Mukai kernels which induces
the canonical adjunction morphism $\Phi_{E}^{\text {aadj }} \Phi_{E} \rightarrow$ Id in case where $E$ is a pushforward of an object on some $Z \hookrightarrow X_{1} \times X_{2}$.

Let $X_{1}$ and $X_{2}$ be a pair of separable schemes of finite type over $k$. Let $Z \xrightarrow{\iota_{Z}} X_{1} \times X_{2}$ be a closed immersion proper over both $X_{1}$ and $X_{2}$. Denote by $\pi_{Z 1}$ the composition $Z \xrightarrow{\iota_{Z}}$ $X_{1} \times X_{2} \xrightarrow{\pi_{1}} X_{1}$. Consider the following fiber squares:

Then $Z^{\prime}=\left(Z \times X_{1}\right) \cap\left(X_{1} \times Z\right) \xrightarrow{\iota_{Z}^{\prime}} X_{1} \times X_{2} \times X_{1}$ fits into the fiber square

Let $\sigma_{\Delta}$ denote the square obtained from (4.17) by base change $X_{1} \times X_{2} \xrightarrow{\Delta} X_{1} \times X_{2} \times X_{1}$ :

Observe that:

- Composition $Z \xrightarrow{\Delta} Z^{\prime} \xrightarrow{\iota_{Z^{\prime}}} X_{1} \times X_{1} \times X_{1}$ equals $Z \xrightarrow{\pi_{Z 1}} X_{1} \xrightarrow{\Delta} X_{1} \times X_{1}$.
- Compositions $Z \xrightarrow{\Delta} Z^{\prime} \xrightarrow{l_{12}^{\prime}} Z \times X_{1} \xrightarrow{\pi_{Z 12}} Z$ and $Z \xrightarrow{\Delta} Z \times X_{1} \xrightarrow{\pi_{Z 12}} Z$ are the identity map.
- Compositions $Z \xrightarrow{\Delta} Z^{\prime} \xrightarrow{t_{23}^{\prime}} X_{1} \times Z \xrightarrow{\pi_{Z 23}} Z$ and $Z \xrightarrow{\Delta} X_{1} \times Z \xrightarrow{\pi_{Z 23}} Z$ are the identity map.

Theorem 4.1. Let $E_{Z} \in D(Z)$ be such that $E=\iota_{Z *}\left(E_{Z}\right)$ is perfect in $D\left(X_{1} \times X_{2}\right)$. Let $\Phi_{E}$ be the Fourier-Mukai transform $D\left(X_{1}\right) \rightarrow D\left(X_{2}\right)$ with kernel $E$. The adjunction counit $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow \mathrm{Id}_{X_{1}}$ is isomorphic to the morphism of Fourier-Mukai transforms induced by the
composition:

$$
\begin{align*}
& Q_{Z}=\pi_{13 *}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z 23 *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)\right) \\
& \downarrow^{\pi_{13 *} \kappa_{\sigma}} \\
& \pi_{13 *} \iota_{Z^{\prime} *}\left(\iota_{12}^{*} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{23}^{*} \pi_{Z 23}^{*} \mathbf{R} \operatorname{Hom}\left(E_{Z}, \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)\right) \\
& \downarrow^{\pi_{13 *} l^{\prime} Z^{*} \beta_{\Delta}} \\
& \pi_{13 *} \iota Z^{\prime} * \Delta_{*} \Delta^{*}\left(\iota_{12}^{\prime *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{23}^{\prime *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)\right) \\
& \simeq \downarrow \Delta_{*} \pi_{Z 1 *}\left(\left(\zeta_{\pi_{Z 12},{ }_{12}^{\prime}, \Delta} \otimes \zeta_{\pi Z 23,{ }_{23}^{\prime}, \Delta}\right) \circ v_{\Delta}\right) \circ \eta_{\Delta, \pi_{Z 1} \circ \eta_{\pi_{13},{ }^{\prime} Z^{\prime}}^{-1}, \Delta}  \tag{4.19}\\
& \Delta_{*} \pi_{Z 1 *}\left(E_{Z} \otimes \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)\right) \\
& \downarrow \Delta_{*} \pi_{Z 1 *}\left(\operatorname{ev}_{E_{Z}}\right) \\
& \Delta_{*} \pi_{Z 1 *} \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right) \\
& \begin{array}{l}
\forall \Delta_{*} \epsilon_{\pi_{Z 1}} \\
\Delta_{*} \mathcal{O}_{X_{1}}
\end{array}
\end{align*}
$$

Proof. Assume first that $X_{2}$ is proper. By Theorem 3.1 the adjunction counit $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow \operatorname{Id}_{X_{1}}$ is induced by the morphism of Fourier-Mukai kernels which we reproduce here for the convenience of our readers:

$$
\begin{align*}
& \pi_{13 *}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right)\right)\right) \xrightarrow{\beta_{\Delta}} \pi_{13 *} \Delta_{*} \Delta^{*}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)\right)  \tag{4.20}\\
& \pi_{13 *} \Delta_{*} \Delta^{*}\left(\pi_{12}^{*} E \otimes \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right)\right)\right) \simeq \Delta_{*} \pi_{1 *}\left(E \otimes E^{\vee} \otimes \pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{4.21}\\
& \Delta_{*} \pi_{1 *}\left(E \otimes E^{\vee} \otimes \pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right)\right) \xrightarrow{\Delta_{*} \pi_{1 *}(\mathrm{ev} E \otimes \mathrm{Id})} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right)  \tag{4.22}\\
& \Delta_{*} \pi_{1 *}\left(\pi_{1}^{\prime}\left(\mathcal{O}_{X_{1}}\right)\right) \xrightarrow{\Delta_{*} \epsilon_{\pi_{1}}} \Delta_{*} \mathcal{O}_{X_{1}} . \tag{4.23}
\end{align*}
$$

where the connecting isomorphism (4.21) is $\Delta_{*} \pi_{1 *}\left(\left(\zeta_{\pi_{12}, \Delta} \otimes \zeta_{\pi_{23}, \Delta}\right) \circ \nu_{\Delta}\right) \circ \eta_{\Delta, \pi_{1}} \circ \eta_{\pi_{13}, \Delta}^{-1}$.
We have $E=\iota_{Z *} E_{Z}$ and

$$
\begin{align*}
E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}}=\left(\iota_{Z *} E_{Z}\right)^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}} & \xrightarrow{(2.10)} \mathbf{R} \mathcal{H o m}\left(\iota_{Z *} E_{Z}, \pi_{1}^{!} \mathcal{O}_{X_{1}}\right) \\
& \xrightarrow{\delta_{Z}^{-1}} \quad \iota_{Z *} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right) . \tag{4.24}
\end{align*}
$$

Using the isomorphisms $\pi_{12}^{*} \iota Z * \xrightarrow{\mu_{\sigma_{12}^{T}}} \iota Z 12 * \pi_{Z 12}^{*}$ and $\pi_{23}^{*} \iota Z * \xrightarrow{\mu_{\sigma_{23}^{T}}} \iota_{Z 23 *} \pi_{Z 23}^{*}$ and functoriality of $\beta_{\Delta}$, we see that (4.20) is isomorphic to

$$
\begin{gather*}
\pi_{13 *}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z 23 *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
\downarrow \pi_{13 *} \beta_{\Delta}  \tag{4.25}\\
\pi_{13 *} \Delta_{*} \Delta^{*}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z 23 *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) .
\end{gather*}
$$

By Proposition 4.1 it also follows that (4.22)-(4.23) is isomorphic to the composition

$$
\begin{aligned}
& \Delta_{*} \pi_{1 *}\left(\iota_{Z *} E_{Z} \otimes \iota_{Z *} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right)
\end{aligned}
$$

The connecting isomorphism from (4.25) to (4.26) works out to be

$$
\begin{align*}
& \pi_{13 *} \Delta_{*} \Delta^{*}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} E_{Z} \otimes\right.\left.\iota_{Z 23 *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
& \simeq \downarrow\left(\mu_{\sigma_{Z 12}} \otimes \mu_{\sigma_{Z 23}}\right) \circ v_{\Delta} \\
& \pi_{13 *} \Delta_{*}\left(\iota_{Z *} \Delta^{*} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z *} \Delta^{*} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right)  \tag{4.27}\\
& \simeq \downarrow \Delta_{*} \pi_{1 *}\left(\iota_{Z *} \zeta_{\pi_{Z 12}, \Delta} \otimes \iota \iota_{Z *} \zeta_{\pi_{Z 23}, \Delta}\right) \circ \eta_{\Delta, \pi_{1} \circ \eta_{\pi_{13}, \Delta}^{-1}} \\
& \vee \\
& \Delta_{*} \pi_{1 *}\left(\iota_{Z *} E_{Z} \otimes \iota_{Z *} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) .
\end{align*}
$$

By functoriality the bottom isomorphism of (4.27) commutes with the top morphism of (4.26), so we conclude that $(4.20)-(4.23)$ is isomorphic to the composition of

$$
\begin{align*}
& \pi_{13 *}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z 23 *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
& \downarrow \pi_{13 *} \beta_{\Delta} \\
& \pi_{13 *} \Delta_{*} \Delta^{*}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z 23 *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H} \operatorname{Hom}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
& \simeq \downarrow_{13 *} \Delta_{*}\left(\left(\mu_{Z 12} \otimes \mu_{Z 23}\right) \circ v_{\Delta}\right)  \tag{4.28}\\
& \pi_{13 *} \Delta_{*}\left(\iota_{Z *} \Delta^{*} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{Z *} \Delta^{*} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
& \downarrow \pi_{13 *} \Delta_{*} \kappa_{\sigma_{\Delta}} \\
& \pi_{13 *} \Delta_{*} \iota{ }_{Z *}\left(\Delta^{*} \pi_{Z 12}^{*} E_{Z} \otimes \Delta^{*} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right)
\end{align*}
$$

with

$$
\begin{align*}
& \pi_{13 *} \Delta_{*}{ }^{\iota} Z *\left(\Delta^{*} \pi_{Z 12}^{*} E_{Z} \otimes \Delta^{*} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
& \simeq \downarrow \Delta_{*} \pi_{1 *}\left(\zeta_{\pi_{Z 12}}, \Delta \otimes \zeta_{\pi_{Z 23}}, \Delta\right) \circ \eta_{\Delta, \pi_{1} \circ \eta_{\pi_{13}}^{-1}, \Delta} \\
& \Delta_{*} \pi_{1 *}{ }_{Z *}\left(E_{Z} \otimes \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
& \downarrow \Delta_{* \pi I_{1 *} l Z * \mathrm{ev}_{E_{Z}}} \\
& \Delta_{*} \pi_{1 *} \iota Z *!{ }_{Z} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)  \tag{4.29}\\
& \downarrow \Delta_{*} \pi_{1 * \epsilon_{I Z}} \\
& \Delta_{*} \pi_{1 *} \pi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right) \text {. } \\
& \begin{array}{l}
\quad \Delta_{*} \epsilon_{\pi_{1}} \\
\Delta_{*} \mathcal{O}_{X_{1}} .
\end{array}
\end{align*}
$$

The claim of the theorem follows by applying the base change for Künneth maps of Proposition 4.4(2) to (4.28) and noting that as $\pi_{Z 1}=\pi_{1} \circ \iota_{Z}$ so by compatibility of the ( $f_{*}, f^{\times}$) adjunction with pseudo-functoriality, counits $\pi_{1 *} \epsilon_{l Z}$ and $\epsilon_{\pi_{1}}$ at the bottom of (4.29) compose to give $\epsilon_{\pi_{Z 1}}$.

Suppose now $X_{2}$ is not proper. Then, following Section 3.2, we compactify $X_{2}$ by choosing an open immersion $j: X_{2} \rightarrow \bar{X}_{2}$ with $\bar{X}_{2}$ proper. Similar to the conventions in Section 3.2, we use $j$ to also denote all the compactification maps induced by $j: X_{2} \rightarrow \bar{X}_{2}$ and we put a bar over various objects and morphisms to denote their compactified versions. E.g. we denote the inclusion $Z \xrightarrow{\iota_{Z}} X_{1} \times X_{2} \xrightarrow{j} X_{1} \times \bar{X}_{2}$ by $\bar{\iota}_{Z}$. By the argument above the compactified version of the composition (4.19) gives a morphism $\bar{Q}_{Z} \rightarrow \Delta_{\mathcal{O}_{X_{1}}}$ which induces the compactified adjunction counit $\Phi_{\bar{E}}^{\text {ladj }} \Phi_{\bar{E}} \rightarrow \operatorname{Id}_{X_{1}}$. By the results of Section 3.2 the compactified and the uncompactified adjunction counits are naturally isomorphic, therefore to prove the claim of the theorem it suffices to exhibit an isomorphism $\bar{Q}_{Z} \xrightarrow{\sim} Q_{Z}$ which composed with the uncompactified (4.19) gives the compactified (4.19).

All the morphisms in (4.19) except for the first one are independent of the ambient space $X_{2}$. To be more precise, we have $\bar{\pi}_{13} \circ \bar{\iota}_{Z^{\prime}}=\bar{\pi}_{13} \circ j \circ \iota_{Z^{\prime}}=\pi_{13} \circ{ }_{I^{\prime}}$, and hence the compactified versions of last four morphisms in (4.19) are isomorphic to the uncompactified ones via pseudofunctoriality isomorphisms. It therefore suffices to find an isomorphism $\bar{Q}_{Z} \xrightarrow{\sim} Q_{Z}$ that would make the following diagram commute:

But $\pi_{13 *} \simeq \bar{\pi}_{13 *} j_{*}$ and square $\sigma$ is obtained from square $\bar{\sigma}$ by the base change $j: X_{1} \times X_{2} \times$ $X_{1} \rightarrow X_{1} \times \bar{X}_{2} \times X_{1}$. So the desired statement is precisely the base change for Künneth maps of Proposition 4.4.

We have similarly:
Theorem 4.2. Under the assumptions of Theorem 4.1 let $\Psi_{E}: D\left(X_{2}\right) \rightarrow D\left(X_{1}\right)$ be the Fourier-Mukai transform with kernel E. The adjunction counit $\Psi_{E} \Psi_{E}^{\text {radj }} \rightarrow$ Id is isomorphic to the morphism of Fourier-Mukai transforms induced by the composition:

$$
\begin{align*}
& Q_{Z}^{\prime}=\pi_{13 *}\left(\iota_{Z 12 *} \pi_{Z 12}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \iota_{Z 23 *} \pi_{Z 23}^{*} E_{Z}\right) \\
& \downarrow \pi_{13 * \kappa_{\sigma}} \\
& \pi_{13 * \iota Z^{\prime} *}\left(\pi_{Z 12}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \pi_{Z 23}^{*} E_{Z}\right) \\
& \downarrow^{\pi_{13 *} I^{\prime} * \beta_{\Delta}} \\
& \pi_{13 *}{ }_{Z^{\prime} *} \Delta_{*} \Delta^{*}\left(\pi_{Z 12}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \pi_{Z 23}^{*} E_{Z}^{\vee}\right) \\
& \simeq \downarrow \Delta_{*} \pi_{Z 1 *}\left(\left(\zeta_{\pi_{Z 12}, \iota_{12}^{\prime}}, \Delta \zeta_{\pi_{Z 23},,_{23}^{\prime}, \Delta}\right) \circ v_{\Delta}\right) \circ \eta_{\Delta, \pi_{Z 1}} \circ \eta_{\pi_{13},{ }^{\prime},}^{-1}, \Delta  \tag{4.31}\\
& \Delta_{*} \pi_{Z 1 *}\left(\mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right) \otimes E_{Z}\right) \\
& \downarrow \Delta_{*} \pi_{Z 1 *} \mathrm{ev}_{E_{Z}} \\
& \Delta_{*} \pi_{Z 1 *} \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right) \\
& \begin{array}{l}
\quad \Delta_{*} \epsilon_{\pi_{Z 1}} \\
\Delta_{*} \mathcal{O}_{X_{1}} .
\end{array}
\end{align*}
$$

One of the main advantages of the alternative decompositions offered by Theorems 4.1 and 4.2 is that most of the morphisms in them can become isomorphisms under fairly reasonable assumptions on $Z, X_{1}$ and $X_{2}$. We can then write down twists of $\Phi_{E}$ and $\Psi_{E}$ fairly easily, for example:

Corollary 4.5. Let $X_{1}$ and $X_{2}$ be separable schemes of finite type over a field $k$. Let $Z \xrightarrow{\text { tZ }}$ $X_{1} \times X_{2}$ be a regular closed immersion proper over $X_{1}$ and $X_{2}$. Suppose $\pi_{Z 1 *} \mathcal{O}_{Z}=\mathcal{O}_{X_{1}}$ where $\pi_{Z 1}$ is the composition $Z \xrightarrow{\iota_{Z}} X_{1} \times X_{2} \xrightarrow{\pi_{1}} X_{1}$. Suppose also that $Z \times X_{1}$ and $X_{1} \times Z$ are Tor-independent inside $X_{1} \times X_{2} \times X_{1}$ and denote by $Z^{\prime}$ their intersection. Denote by ${ }^{\prime}{ }_{Z}{ }^{\prime}$ the inclusion $Z^{\prime} \hookrightarrow X_{1} \times X_{2} \times X_{1}$.

Then the Fourier-Mukai kernel of the dual co-twist of $\Phi_{\mathcal{O}_{Z}}: D\left(X_{1}\right) \rightarrow D\left(X_{2}\right)$ is $\pi_{13 *}{ }_{Z^{\prime} *}\left(\mathcal{L} \otimes \mathcal{I}_{\Delta^{\prime}}[1]\right)$ where $\mathcal{I}_{\Delta^{\prime}}$ is the ideal sheaf of the diagonal $Z$ in $Z^{\prime}$ and $\mathcal{L}$ is the pullback of $\pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)$ via $X_{1} \times Z$ to $Z^{\prime}$.

Proof. The Fourier-Mukai kernel of the dual co-twist of $\Phi_{E}$ is the cone of the morphism of kernels underlying $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id. Applying Theorem 4.1, we note that under the assumptions of this corollary, all the morphisms in (4.19) become isomorphisms with the exception of

$$
\begin{gathered}
\pi_{13 *} \iota \iota^{\prime} *\left(\iota_{12}^{\prime *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{23}^{*} \pi_{Z 23}^{*} \mathbf{R} \operatorname{Hom}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) \\
\downarrow^{\pi_{13 *} \iota Z^{\prime} *} \beta_{\Delta} \\
\pi_{13 *} \iota Z^{\prime} * \Delta_{*} \Delta^{*}\left(\iota_{12}^{\prime *} \pi_{Z 12}^{*} E_{Z} \otimes \iota_{23}^{\prime *} \pi_{Z 23}^{*} \mathbf{R} \mathcal{H o m}\left(E_{Z}, \pi_{Z 1}^{!} \mathcal{O}_{X_{1}}\right)\right) .
\end{gathered}
$$

Since $E_{Z}=\mathcal{O}_{Z}$ the above simplifies to the direct image under $\pi_{13 * l^{\prime} * *}$ of

$$
\iota_{23}^{*} \pi_{Z 23}^{*} \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right) \xrightarrow{\beta_{\Delta}} \Delta_{*} \Delta^{*}\left(\iota_{23}^{*} \pi_{Z 23}^{*} \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)\right) .
$$

Write $\mathcal{L}$ for $\iota_{23}^{\prime *} \pi_{Z 23}^{*} \pi_{Z 1}^{!}\left(\mathcal{O}_{X_{1}}\right)$. By Lemma 2.1 (with $f=\mathrm{Id}$ ) the morphism $\mathcal{L} \xrightarrow{\beta_{\Delta}} \Delta_{*} \Delta^{*} \mathcal{L}$ is isomorphic to $\mathcal{L} \otimes\left(\mathcal{O}_{Z^{\prime}} \rightarrow \Delta_{*} \Delta^{*} \mathcal{O}_{Z^{\prime}}\right)$. Since $\mathcal{O}_{Z^{\prime}} \xrightarrow{\beta_{\Delta}} \Delta_{*} \Delta^{*} \mathcal{O}_{Z^{\prime}}$ is just the sheaf restriction $\mathcal{O}_{Z^{\prime}} \rightarrow \Delta_{*} \mathcal{O}_{Z}$, its cone is $\mathcal{I}_{\Delta^{\prime}}[1]$ and the claim follows.

## 5. An example

Let us give a concrete example of using the results of Section 4. For this example we choose the naive derived category transform induced by the Mukai flop. This transform is not an equivalence - it was proved by Namikawa in [17] by direct comparison of Hom spaces. Below we use Corollary 4.5 to compute the kernel which defines its dual co-twist as the Fourier-Mukai transform. We stress that the value of this section lies not in the answer itself, but in demonstrating how the methods of the paper apply to obtain it. However, the reader may observe that the kernel we obtain is a line bundle supported on the zero-section of the product. We shall demonstrate in [1] that this is the reason for the braiding which occurs between natural spherical twists in the derived categories of the cotangent bundles of complete flag varieties (see [11], Section 4).

Let $V$ be a 3-dimensional vector space and let $X_{1}$ be the scheme $T^{*} \mathbb{P}(V)$, that is the total space of the cotangent bundle of $\mathbb{P}(V)$. Similarly, let $X_{2}$ be the scheme $T^{*} \mathbb{P}\left(V^{\vee}\right)$. These schemes admit the following description:

$$
\begin{aligned}
& X_{1}=\left\{0 \stackrel{\alpha}{\stackrel{\alpha}{\subset} U_{1} \stackrel{\alpha}{\subset} V}\right\} \\
& :=\left\{U_{1} \subset V, \alpha \in \operatorname{End}(V) \mid \operatorname{dim} U_{1}=1, \alpha(V) \subseteq U_{1}, \alpha\left(U_{1}\right)=0\right\} \\
& X_{2}=\left\{0 \stackrel{\alpha}{\stackrel{\alpha}{\subset} U_{2} \stackrel{\alpha}{\subset} V}\right\} \\
& :=\left\{U_{2} \subset V, \alpha \in \operatorname{End}(V) \mid \operatorname{dim} U_{2}=2, \alpha(V) \subseteq U_{2}, \alpha\left(U_{2}\right)=0\right\} .
\end{aligned}
$$

We also have a variety

$$
Z=\left\{0^{<} \subset U_{1}^{\alpha} \subset U_{2} \subset V\right\}
$$

with natural "forgetful" maps $\phi_{k}: Z \rightarrow X_{k}$ which forget one of the subspaces. Each map $\phi_{k}$ is isomorphic to the blow-up of the zero section carved out by $\alpha=0$ in $X_{k}$. Both blowups have the same exceptional divisor $F \subset Z$ which is carved out by $\alpha=0$ :

$$
F=\left\{0 \subset U_{1} \subset U_{2} \subset V\right\}
$$

The resulting birational transformation $X_{1} \rightarrow X_{2}$ which transforms the zero-section $\mathbb{P}(V) \hookrightarrow$ $X_{1}$ into the zero-section $\mathbb{P}\left(V^{\vee}\right) \hookrightarrow X_{2}$ is a local model of a four-dimensional Mukai flop. Note that maps $\phi_{k}$ are proper and, since each map $\phi_{k}$ is a blowup of $X_{k}$, we have $\phi_{k *} \mathcal{O}_{Z}=\mathcal{O}_{X_{k}}$.

Let $\Phi$ be the functor $\phi_{2 *} \phi_{1}^{*}$ from $D\left(X_{1}\right)$ to $D\left(X_{2}\right)$ and let us compute its dual co-twist. The functor $\Phi$ is a Fourier-Mukai transform with the kernel $\iota_{Z *} \mathcal{O}_{Z}$, where $\iota_{Z}=\phi_{1} \times \phi_{2}: Z \rightarrow$ $X_{1} \times X_{2}$. We have:

$$
\begin{aligned}
& X_{1} \times X_{2} \times X_{1}=\left\{0^{\left.\stackrel{\alpha_{1}, \alpha_{2}, \alpha_{1}^{\prime}}{{ }_{C}}, U_{1}, U_{1} \subset U_{1}^{\prime} \subset V\right\}}\right.
\end{aligned}
$$

It follows that $Z^{\prime}=\left(Z \times X_{1}\right) \cap\left(X_{1} \times Z\right) \subset X_{1} \times X_{2} \times X_{1}$ can be described as

$$
Z^{\prime}=\left\{\begin{array}{cc|c} 
& \alpha \\
0<U_{1}, U_{1}^{\prime} \subset U_{2} \subset \\
\subset & \alpha & \alpha(V) \subseteq U_{1} \cap U_{1}^{\prime}
\end{array}\right\} .
$$

Observe that for any point of $Z^{\prime}$ we have $U_{1}=U_{1}^{\prime}$ or $\alpha=0$ (or both). Therefore $Z^{\prime}$ consists of two irreducible components: the diagonal $\Delta Z$ and the zero section

$$
P=\left\{0 \subset U_{1}, U_{1}^{\prime} \subset U_{2} \subset V\right\}
$$

The intersection $\Delta Z \cap P$ considered as a subvariety of $\Delta Z$ is the exceptional divisor $F$ of the blowups $Z \xrightarrow{\phi_{i}} X_{i}$ described above. On the other hand, let $P \xrightarrow{\phi_{13}} \mathbb{P}(V) \times \mathbb{P}(V)$ be the map which forgets the subspace $U_{2}$. It is the blowup of the diagonal of $\mathbb{P}(V) \times \mathbb{P}(V)$ and its exceptional divisor in $P$ is carved out by $U_{1}=U_{1}^{\prime}$, i.e. it is $F=\Delta Z \cap P$ again.

By Corollary 4.5 the dual co-twist of $\Phi$ is the Fourier-Mukai transform $X_{1} \rightarrow X_{1}$ with kernel

$$
K=\pi_{13 * l} Z^{\prime} *\left(\mathcal{L} \otimes \mathcal{I}_{\Delta}[1]\right) \in D\left(X_{1} \times X_{1}\right) .
$$

Here $\iota_{Z^{\prime}}$ is the inclusion $Z^{\prime} \hookrightarrow X_{1} \times X_{2} \times X_{1}, \mathcal{I}_{\Delta}$ is the ideal sheaf of $\Delta Z$ in $Z^{\prime}$ and $\mathcal{L}$ is the pullback of $\phi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)$ to $Z^{\prime}$ via $X_{1} \times Z$.

Since $Z \xrightarrow{\phi_{1}} X_{1}$ is the blow-up of the zero-section $\mathbb{P}(V) \hookrightarrow X_{1}$ whose codimension is 2 , we know that $\phi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)$ is the line bundle $\mathcal{O}_{Z}(F)$ where $F$ is the exceptional divisor of the blow-up. On the other hand, pulling back along the projection

$$
Z \rightarrow \mathbb{P}(V) \times \mathbb{P}\left(V^{\vee}\right)
$$

induces an isomorphism
Pic $Z \simeq \operatorname{Pic} \mathbb{P}(V) \times \operatorname{Pic} \mathbb{P}\left(V^{\vee}\right)$.
A simple calculation shows that $\mathcal{O}_{Z}(F)$ is the pullback of $\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}\left(V^{\vee}\right)}(-1,-1)$. Similarly

$$
\operatorname{Pic} Z^{\prime} \simeq \operatorname{Pic} \mathbb{P}(V) \times \operatorname{Pic} \mathbb{P}\left(V^{\vee}\right) \times \operatorname{Pic} \mathbb{P}(V)
$$

and $\mathcal{L}$, being the pullback to $Z^{\prime}$ of $\phi_{1}^{!}\left(\mathcal{O}_{X_{1}}\right)$ via $X_{1} \times Z$, is then the pullback of $\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}\left(V^{\vee}\right) \times \mathbb{P}(V)}(0,-1,-1)$.

Since $Z^{\prime}$ has two irreducible components $\Delta Z$ and $P$, we have $\mathcal{I}_{\Delta} \simeq \iota_{P *} \mathcal{O}_{P}(-\Delta Z \cap P)$
 A simple computation shows that $\mathcal{O}_{P}(-F)$ is the pullback of $\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}\left(V^{\vee}\right) \times \mathbb{P}(V)}(-1,1,-1)$ and therefore $\iota_{P}^{*} \mathcal{L} \otimes \mathcal{O}_{P}(-F)$ is the pullback of $\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}\left(V^{\vee}\right) \times \mathbb{P}(V)}(-1,0,-2)$. We conclude that $K \simeq \pi_{13 *}{ }^{l} Z^{\prime} *{ }^{l} P_{P *} \phi_{13}^{*}\left(\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}(V)}(-1,-2)[1]\right)$.

Now observe that the following diagram commutes

where $\iota_{0}$ is the zero-section inclusion of $\mathbb{P}(V) \times \mathbb{P}(V)$ into $X_{1} \times X_{1}$. We conclude that

$$
K \simeq \iota_{0 *} \phi_{13 *} \phi_{13}^{*}\left(\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}(V)}(-1,-2)[1]\right) \simeq \iota_{0 *}\left(\mathcal{O}_{\mathbb{P}(V) \times \mathbb{P}(V)}(-1,-2)[1]\right)
$$

## Acknowledgments

The authors would like to thank Alexei Bondal and Paul Bressler for useful discussions. The authors would like to thank an anonymous referee for major improvements to all aspects of the paper. The first author would like to thank the Department of Mathematics of the University of Chicago for their support. The second author would like to thank the University of Liverpool, the Max-Planck-Institut für Mathematik and the Steklov Mathematical Institute for their hospitality during his work on this paper.

## Appendix. The unabridged proof of Theorem 3.1

Here we give a complete version of the proof of Theorem 3.1. It contains explicit computations of all the connecting isomorphisms which we left out of the version in the main body of the paper so as to emphasize the meaningful part of the proof. The version below is for referees and others who relish seeing how the monoidal structure of the inverse image functor commutes with pseudofunctoriality and with the associativity of tensor product. Lasciate ogne speranza, voi ch'intrate.

Proof. Set

$$
Q^{\prime}=\pi_{23}^{*}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee}\right) \otimes \pi_{12}^{*} E
$$

so that $Q=\pi_{13 *} Q^{\prime}$. Since $\pi_{12} \circ \Delta=\pi_{23} \circ \Delta=\mathrm{Id}$ we have a natural isomorphism

$$
\begin{align*}
& \Delta^{*} Q^{\prime} \xrightarrow{\nu_{\Delta}} \Delta^{*} \pi_{23}^{*}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee}\right) \otimes \Delta^{*} \pi_{12}^{*} E \\
& \xrightarrow{\zeta_{\pi_{23}, \Delta} \otimes \zeta_{\pi_{12}, \Delta}}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes E^{\vee}\right) \otimes E . \tag{A.1}
\end{align*}
$$

We therefore define a morphism

$$
\begin{equation*}
\Delta^{*} Q^{\prime} \xrightarrow{(\mathrm{A} .1)}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes E^{\vee}\right) \otimes E \xrightarrow{E \otimes\left(E^{\vee} \otimes(-)\right) \rightarrow \mathrm{Id}} \pi_{1}^{!} \mathcal{O}_{X_{1}} \tag{A.2}
\end{equation*}
$$

In these terms, the morphism of FM-transforms $D(X) \rightarrow D(X)$ induced by $Q \xrightarrow{(3.3)-(3.6)}$ $\Delta \mathcal{O}_{X}$ is:

$$
\begin{align*}
& \tilde{\pi}_{2 *}\left(\pi_{13 *} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\mathrm{Id} \rightarrow \Delta_{*} \Delta^{*}} \tilde{\pi}_{2 *}\left(\pi_{13 *} \Delta_{*} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right)  \tag{A.3}\\
& \tilde{\pi}_{2 *}\left(\pi_{13 *} \Delta_{*} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\eta_{\Delta, \pi_{1}} \circ \eta_{\pi_{13}, \Delta}^{-1}} \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right)  \tag{A.4}\\
& \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \Delta^{*} Q^{\prime} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{(\mathrm{A} .2)} \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \tilde{\pi}_{1}^{*}(-)\right)  \tag{A.5}\\
& \tilde{\pi}_{2 *}\left(\Delta_{*} \pi_{1 *} \pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\pi_{1 *} \pi_{1}^{\prime} \rightarrow \mathrm{Id}} \tilde{\pi}_{2 *}\left(\Delta_{*} \mathcal{O}_{X_{1}} \otimes \tilde{\pi}_{1}^{*}(-)\right) . \tag{A.6}
\end{align*}
$$

On the other hand, $\Phi_{E}$ is the composition of functors $\pi_{1}^{*}, E \otimes(-)$ and $\pi_{2 *}$. Each of these functors has a left adjoint, these adjoints are $\pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes-\right), E^{\vee} \otimes(-)$ and $\pi_{2}^{*}$, respectively. Therefore, the adjunction counit $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id is the composition of the three corresponding adjunction counits:

$$
\begin{align*}
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes \pi_{2}^{*} \pi_{2 *}\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right) \\
& \xrightarrow{\pi_{2}^{*} \pi_{2 *} \rightarrow \mathrm{Id}} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right)  \tag{A.7}\\
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right) \xrightarrow{E^{\vee} \otimes(E \otimes(-)) \rightarrow \mathrm{Id}} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*}(-)\right)  \tag{A.8}\\
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*}(-)\right) \rightarrow \mathrm{Id} . \tag{A.9}
\end{align*}
$$

The claim of the theorem is that the composition (A.7)-(A.9) is isomorphic to the composition (A.3)-(A.6)

Let us clarify some terminology. We say that two morphisms of functors $f \rightarrow g$ and $f^{\prime} \rightarrow g^{\prime}$ are isomorphic if there exist connecting isomorphisms $f \xrightarrow{\sim} f^{\prime}$ and $g \xrightarrow{\sim} g^{\prime}$ such that the diagram

commutes. Clearly it is an equivalence relation on the set of all morphisms between all functors between two given categories. In particular, it is transitive.

If we further have a morphism of functors $g \rightarrow h$ which is isomorphic to a morphism of functors $g^{\prime \prime} \rightarrow h^{\prime \prime}$ then $f \rightarrow g \rightarrow h$ is isomorphic to $f^{\prime} \rightarrow g^{\prime} \xrightarrow{\sim} g^{\prime \prime} \rightarrow h^{\prime \prime}$, where the connecting isomorphism $g^{\prime} \xrightarrow{\sim} g^{\prime \prime}$ is the composition of the inverse of the connecting isomorphism $g \xrightarrow{\sim} g^{\prime}$ with the connecting isomorphism $g \xrightarrow{\sim} g^{\prime \prime}$.

Our strategy therefore is to consecutively replace the morphisms which compose (3.19)-(3.21) by isomorphic ones until we obtain (3.15)-(3.18).

Observe that the following diagram, whose vertical arrows are all isomorphisms, commutes:

The first square in it commutes by functoriality of $\rho^{-1}$, the second commutes by Lemma 3.2, the third commutes by Lemma 2.1, the fourth commutes by functoriality of $\beta_{\Delta}$ and the fifth commutes tautologically.

We now want to simplify the connecting isomorphism in the right column of (A.11). By compatibility of the projection formula with pseudofunctoriality (see diagram (2.29)) we have an equality

$$
\alpha_{\Delta} \circ \alpha_{\pi_{23}} \circ\left(\operatorname{Id} \otimes \eta_{\pi_{23}, \Delta}\right)=\left(\zeta_{\pi_{23}, \Delta}^{-1} \otimes \mathrm{Id}\right) \circ \eta_{\pi_{23}, \Delta} \circ\left(\alpha_{\pi_{23} \circ \Delta}\right)
$$

of two morphisms

$$
\begin{aligned}
& \left(E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \Delta^{*} \pi_{12}^{*}\left(E \otimes \pi_{1}^{*}(-)\right) \\
& \quad \longrightarrow \pi_{23 *} \Delta_{*}\left(\Delta^{*} \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \Delta^{*} \pi_{12}^{*}\left(E \otimes \pi_{1}^{*}(-)\right)\right)
\end{aligned}
$$

Since $\pi_{23} \circ \Delta=\mathrm{Id}$, we have $\alpha_{\pi_{23} \circ}=\mathrm{Id}$. It follows that the right-hand column of (A.11) equals to

$$
\begin{align*}
& \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right)  \tag{A.12}\\
& \downarrow^{\rho^{-1}} \\
& \pi_{1 *}\left(\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right) \\
& \downarrow\left(\zeta_{\pi_{23}, \Delta^{\otimes \zeta} \xi_{\pi_{12}}^{-1}, \Delta}^{-1} \circ \eta_{\pi_{23}, \Delta}\right. \\
& \pi_{1 * \pi_{23 *}} \Delta_{*}\left(\Delta^{*} \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes \Delta^{*} \pi_{12}^{*}\left(E \otimes \pi_{1}^{*}(-)\right)\right) \\
& \left.\downarrow{ }^{\nu} \Delta^{\circ \rho \rho^{-1} \circ\left(\mathrm{Id} \otimes v \pi_{12}\right.}\right){ }^{\circ \nu_{\Delta}^{-1}} \\
& \pi_{1 * \pi_{23 *}} \Delta_{*}\left(\Delta^{*}\left(\pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes \pi_{12}^{*} E\right) \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) \text {. }
\end{align*}
$$

Note that $v_{\Delta}^{-1}$ and $\operatorname{Id} \otimes v_{\pi_{12}}$ commute by functoriality. Note further, that by the compatibility of the map $v_{\Delta}$ with the associativity of the tensor product (see diagram (2.25)) we have an equality

$$
v_{\Delta} \circ \rho^{-1} \circ v_{\Delta}^{-1}=\left(v_{\Delta}^{-1} \otimes \mathrm{Id}\right) \circ \rho^{-1} \circ\left(\mathrm{Id} \otimes v_{\Delta}\right)
$$

of two morphisms

$$
\begin{aligned}
& \Delta^{*} \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \Delta^{*}\left(\pi_{12}^{*} E \otimes \pi_{12}^{*} \pi_{1}^{*}(-)\right) \\
& \quad \longrightarrow \Delta^{*}\left(\pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{!} \mathcal{O}_{X_{1}}\right) \otimes \pi_{12}^{*} E\right) \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)
\end{aligned}
$$

It follows that composition (A.12) equals to

$$
\begin{align*}
& \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right)  \tag{A.13}\\
& \downarrow^{\rho^{-1}} \\
& \pi_{1 *}\left(\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right) \\
& \downarrow\left(\zeta_{\left.\pi_{23}, \Delta^{\otimes}\left(\nu \Delta \circ \vee \tau_{12} \circ \zeta_{\pi_{12}}^{-1}, \Delta\right)\right) \circ \eta_{\pi_{23}, \Delta}, ~}^{\text {, }}\right. \\
& \pi_{1 *} \pi_{23 *} \Delta_{*}\left(\Delta^{*} \pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes\left(\Delta^{*} \pi_{12}^{*} E \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right)\right) \\
& \downarrow\left(v_{\Delta}^{-1} \otimes \mathrm{\otimes d}\right) \circ \rho^{-1} \\
& \pi_{1 *} \pi_{23 *} \Delta_{*}\left(\Delta^{*}\left(\pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes \pi_{12}^{*} E\right) \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) \text {. }
\end{align*}
$$

By compatibility of $v$ with pseudofunctoriality (see diagram (2.26)) we have an equality

$$
v_{\Delta} \circ v_{\pi_{12}} \circ \zeta_{\pi_{12}, \Delta}^{-1}=v_{\pi_{12} \circ \Delta} \circ\left(\zeta_{\pi_{12}, \Delta}^{-1} \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right)
$$

of morphisms

$$
E \otimes \pi_{1}^{*}(-) \longrightarrow \Delta^{*} \pi_{12}^{*} E \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)
$$

Since $\pi_{12} \circ \Delta=$ Id we further have $\nu_{\pi_{12} \circ} \Delta=\mathrm{Id}$. Therefore

$$
\left(\zeta_{\pi_{23}, \Delta}^{-1} \otimes\left(v_{\Delta} \circ v_{\pi_{12}} \circ \zeta_{\pi_{12}, \Delta}^{-1}\right)\right) \circ \eta_{\pi_{23}, \Delta}=\left(\zeta_{\pi_{23}, \Delta}^{-1} \otimes\left(\zeta_{\pi_{12}, \Delta}^{-1} \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right)\right) \circ \eta_{\pi_{23}, \Delta}
$$

in (A.13). Finally, by functoriality of $\rho$ and of $\eta_{\pi_{23}, \Delta}$ we have

$$
\begin{aligned}
& \rho^{-1} \circ\left(\zeta_{\pi_{23}, \Delta}^{-1} \otimes\left(\zeta_{\pi_{12}, \Delta}^{-1} \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right)\right) \circ \eta_{\pi_{23}, \Delta} \\
& \quad=\left(\left(\zeta_{\pi_{23}, \Delta}^{-1} \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right) \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right) \circ \eta_{\pi_{23}, \Delta} \circ \rho^{-1}
\end{aligned}
$$

We conclude that (A.13) equals to

$$
\begin{gather*}
\pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right)  \tag{A.14}\\
\downarrow_{\rho^{-1} \circ \rho^{-1}} \\
\pi_{1 *}\left(\left(\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes E\right) \otimes \pi_{1}^{*}(-)\right) \\
\downarrow\left(\left(v_{\Delta}^{-1} \circ\left(\zeta_{\pi_{23}, \Delta^{-1}}^{-1} \zeta_{\pi_{12}, \Delta}^{-1}\right)\right) \otimes \xi_{\pi_{12}, \Delta}^{-1}\right) \circ \eta_{\pi_{23}, \Delta} \\
\pi_{1 *} \pi_{23 *} \Delta_{*}\left(\Delta^{*}\left(\pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes \pi_{12}^{*} E\right) \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) .
\end{gather*}
$$

Recall now that we write $Q^{\prime}$ for $\pi_{23}^{*}\left(E^{\vee} \otimes \pi_{1}^{\prime} \mathcal{O}_{X_{1}}\right) \otimes \pi_{12}^{*} E$ and note that $v_{\Delta}^{-1} \circ\left(\zeta_{\pi_{23}, \Delta}^{-1} \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right)$ in (A.14) is precisely the inverse of isomorphism (A.1). So what we have shown above is that (A.7) is isomorphic to

$$
\begin{equation*}
\pi_{1 *} \pi_{23 *}\left(Q^{\prime} \otimes \pi_{12}^{*} \pi_{1}^{*}(-)\right) \xrightarrow{v_{\Delta} \circ \beta_{\Delta}} \pi_{1 *} \pi_{23 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) \tag{A.15}
\end{equation*}
$$

with the connecting isomorphism on the RHS being

$$
\begin{aligned}
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right) \\
& \xrightarrow{\left((\mathrm{A} .1)^{-1} \otimes \zeta_{\pi_{12}, \Delta}^{-1}\right) \circ \eta_{\pi_{23}, \Delta \circ \rho^{-1} \circ \rho^{-1}} \pi_{1 *} \pi_{23 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) .} .
\end{aligned}
$$

As $\pi_{1} \circ \pi_{23}=\tilde{\pi}_{2} \circ \pi_{13}$ and $\pi_{1} \circ \pi_{12}=\tilde{\pi}_{1} \circ \pi_{13}$ (see diagram (3.1)) we have the following commutative square

$$
\begin{aligned}
& \pi_{1 *} \pi_{23 *}\left(Q^{\prime} \otimes \pi_{12}^{*} \pi_{1}^{*}(-)\right) \xrightarrow{(\mathrm{A} .15)} \pi_{1 *} \pi_{23 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{12}^{*} \pi_{1}^{*}(-)\right) \\
& \left(\operatorname{Id\otimes }\left(\zeta_{\pi_{1}, \pi_{13}}^{-1} \circ \zeta_{\pi_{1}, \pi_{12}}\right)\right) \circ \eta_{\tilde{\pi}_{2}, \pi_{13}} \circ \eta_{\pi_{1}, \pi_{23}}^{-1} \downarrow \downarrow\left(\operatorname{Id\otimes }\left(\zeta_{\bar{\pi}_{1}, \pi_{13}}^{-1} \circ \zeta_{\pi_{1}, \pi_{12}}\right)\right) \circ \circ \eta_{\tilde{\pi}_{2}, \pi_{13}} \circ \eta_{\pi_{1}, \pi_{23}}^{-1} \\
& \tilde{\pi}_{2 *} \pi_{13 *}\left(Q^{\prime} \otimes \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow[v_{\Delta} \circ \beta_{\Delta}]{\longrightarrow} \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) .
\end{aligned}
$$

We finally conclude that (A.7) is isomorphic to

$$
\begin{equation*}
\tilde{\pi}_{2 *} \pi_{13 *}\left(Q^{\prime} \otimes \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\nu_{\Delta} \circ \beta_{\Delta}} \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \tag{A.16}
\end{equation*}
$$

with the connecting isomorphism on the RHS being

$$
\begin{align*}
& \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right) \\
& \quad \xrightarrow{\left((\mathrm{A} .1)^{-1} \otimes \zeta_{\tilde{\pi}_{1}, \pi_{13}, \Delta}^{-1}\right) \circ \eta_{\tilde{\pi}_{2}, \pi_{13}, \Delta^{\circ} \rho^{-1} \circ \rho^{-1}}^{\longrightarrow}} \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) . \tag{A.17}
\end{align*}
$$

Here we have used the fact that by pseudofunctoriality relations (2.19) and (2.20) we have

$$
\eta_{\tilde{\pi}_{2}, \pi_{13}} \circ \eta_{\pi_{1}, \pi_{23}}^{-1} \circ \eta_{\pi_{23}, \Delta}=\eta_{\tilde{\pi}_{2}, \pi_{13}} \circ \eta_{\pi_{1} \circ \pi_{23}, \Delta}=\eta_{\tilde{\pi}_{2}, \pi_{13}} \circ \eta_{\tilde{\pi}_{2} \circ \pi_{13}, \Delta}=\eta_{\tilde{\pi}_{2}, \pi_{13}, \Delta}
$$

and similarly $\zeta_{\tilde{\pi}_{1}, \pi_{13}}^{-1} \circ \zeta_{\pi_{1}, \pi_{12}} \circ \zeta_{\pi_{12}, \Delta}^{-1}=\zeta_{\tilde{\pi}_{1}, \pi_{13}, \Delta}^{-1}$.

Next, we note that the following diagram commutes:

$$
\begin{align*}
& \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes\left(E^{\vee} \otimes\left(E \otimes \pi_{1}^{*}(-)\right)\right)\right) \xrightarrow{(\mathrm{A} .8)} \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*}(-)\right) \tag{A.18}
\end{align*}
$$

$$
\begin{aligned}
& \left(\mathrm{Id} \otimes \zeta_{\tilde{\pi}_{1}, \Delta}^{-1}\right) \stackrel{\circ \eta_{\tilde{\pi}_{2}}, \Delta}{ } \downarrow \quad{ }^{(\mathrm{A}, 2)}\left(\mathrm{I} \otimes \zeta_{\tilde{\pi}_{1}, \Delta}^{-1}\right) \circ \eta_{\tilde{\pi}_{2}, \Delta} \\
& \tilde{\pi}_{2 *} \Delta * \pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{(A, 2)} \tilde{\pi}_{2 *} \Delta * \pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) .
\end{aligned}
$$

Here the top square commutes by Lemma 2.3, the second square commutes by the definition of map (A.2) and the third square commutes by the functoriality. Therefore (A.8) is isomorphic to

$$
\begin{equation*}
\tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{(\mathrm{A} .2)} \tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) . \tag{A.19}
\end{equation*}
$$

And finally, the following square
commutes by functoriality. Therefore (A.9) is isomorphic to

$$
\begin{equation*}
\tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\pi_{1}^{!} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*} \Delta_{*} \tilde{\pi}_{1}^{*}(-)\right) \xrightarrow{\pi_{1 *}\left(\pi_{1}^{\prime} \mathcal{O}_{X_{1}} \otimes \pi_{1}^{*}(-)\right) \rightarrow \mathrm{Id}} \tilde{\pi}_{2 *} \Delta_{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-) . \tag{A.21}
\end{equation*}
$$

We now compute the connecting isomorphisms. Composing the inverse of (A.17), the isomorphism in the right column of (A.11), with the isomorphism in the left column of (A.18) we obtain

$$
\begin{aligned}
& \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \\
& \quad \xrightarrow{\left(\operatorname{Id} \otimes\left(\zeta_{\tilde{\pi}_{1}, \Delta^{\circ}}^{-1} \tilde{\zeta}_{1}, \pi_{13}, \Delta\right)\right) \circ \eta_{\tilde{\pi}_{2}, \Delta \eta_{\tilde{\pi}_{2}, \pi_{13}, \Delta}^{-1}}^{l} \tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right)}
\end{aligned}
$$

and by pseudofunctoriality relations (2.19) and (2.20) this is equal to

$$
\begin{align*}
& \tilde{\pi}_{2 *} \pi_{13 *} \Delta_{*}\left(\Delta^{*} Q^{\prime} \otimes \Delta^{*} \pi_{13}^{*} \tilde{\pi}_{1}^{*}(-)\right) \\
& \quad \xrightarrow{\left(\mathrm{Id} \otimes\left(\zeta_{\Delta, \pi_{1}}^{-1} \circ \zeta_{\pi_{13}, \Delta}\right)\right) \circ \eta_{\Delta, \pi_{1}} \circ \eta_{\pi_{13}, \Delta}^{-1}} \tilde{\pi}_{2 *} \Delta_{*} \pi_{1 *}\left(\Delta^{*} Q^{\prime} \otimes \pi_{1}^{*} \Delta^{*} \tilde{\pi}_{1}^{*}(-)\right) . \tag{A.22}
\end{align*}
$$

On the other hand, the composition of the inverse of the isomorphism in the right column of (A.18) with the isomorphism in the left column of (A.20) is clearly Id.

We can now conclude that the adjunction counit $\Phi_{E}^{\text {ladj }} \Phi_{E} \rightarrow$ Id, being the composition of (A.7)-(A.9), is isomorphic to the composition of (A.16), (A.22), (A.19) and (A.21). The claim
of the theorem then follows from the fact that the following diagram commutes:

where the horizontal isomorphisms are all due to the projection formula. To see that diagram (A.23) indeed commutes, observe that its topmost square commutes by Lemma 2.1, the middle two commute by functoriality and the lowermost square commutes by Lemma 2.2.

[^1]:    ${ }^{1}$ In a non-noetherian world one can work with a more general notion of a quasi-proper scheme map, cf. [13, Section 4.3].

[^2]:    ${ }^{2}$ I.e. over a point. One can obtain duality theories on $X$ relative to any separated, finite-type map $\pi_{S}: X \rightarrow S$ with $S$ noetherian, but only after restricting to objects of $D(X)$ perfect over $S$ (see [8], Cor. 4.9.2 etc.). Since the objects perfect over a point are precisely the complexes with bounded and coherent cohomologies, the global duality works for all of $D(X)$.
